GENERALIZED VAN DER POL EQUATION AND
HILBERT’S 16TH PROBLEM

XENAKIS IOAKIM

Abstract. In this article, we study the bifurcation of limit cycles from the
harmonic oscillator \( \dot{x} = y, \dot{y} = -x \) in the system
\[
\dot{x} = y, \quad \dot{y} = -x + \varepsilon f(y)(1 - x^2),
\]
where \( \varepsilon \) is a small positive parameter tending to 0 and \( f \) is an odd polynomial
of degree \( 2n + 1 \), with \( n \) an arbitrary but fixed natural number. We prove
that, the above differential system, in the global plane, for particularly chosen
odd polynomials \( f \) of degree \( 2n + 1 \) has exactly \( n + 1 \) limit cycles and that
this number is an upper bound for the number of limit cycles for every case
of an arbitrary odd polynomial \( f \) of degree \( 2n + 1 \). More specifically, the
existence of the limit cycles, which is the first of the main results in this
work, is obtained by using the Poincaré’s method, and the upper bound for
the number of limit cycles can be derived from the work of Iliev [4]. We also
investigate the possible relative positions of the limit cycles for this differential
system, which is the second main problem studying in this work. In particular,
we construct differential systems with \( n \) given limit cycles and one limit cycle
whose position depends on the position of the previous \( n \) limit cycles. Finally,
we give some examples in order to illustrate the general theory presented in
this work.

1. Introduction

1.1. Generalized Van der Pol equation and statement of the main results.
In this article, we study the second part of Hilbert’s 16th problem for a generalized
Van der Pol equation. More specifically, we consider the system
\[
\dot{x} = y, \quad \dot{y} = -x + \varepsilon f(y)(1 - x^2),
\]
where \( f \) is an odd polynomial of degree \( 2n + 1 \), with \( n \) an arbitrary but fixed natural number and \( 0 < \varepsilon \ll 1 \). System (1.1) reduces to the Van der Pol equation
for \( f(y) = y \). Our purpose here is to find an upper bound for the number of
limit cycles for system (1.1), depending only on the degree of its polynomials and
investigate their relative positions.
where $f$ is an odd polynomial of degree $2n+1$, with $n$ an arbitrary but fixed natural number and $0 < \varepsilon \ll 1$. The problem is to find an upper bound for the number of limit cycles for equation (1.2), depending only on the degree $2n+1$ of the odd polynomial $f$ and investigate their relative positions. We prove that the generalized Van der Pol equation (1.2) has exactly $n + 1$ limit cycles for particularly chosen odd polynomials $f$ of degree $2n+1$ and that this number is an upper bound for the number of limit cycles for every case of an arbitrary odd polynomial $f$ of degree $2n+1$. Furthermore, we show how to construct these polynomials of equation (1.2) which attain that upper bound. On the possible relative positions of the $n + 1$ limit cycles we show that there exists a limit cycle whose position depends on the degree and that this number is an upper bound for the position of the rest $n$ limit cycles (actually, this limit cycle is close to the circle with the dependent radius (see Definition 1.13)).

Now, we state the main results of this article, which are the following theorems.

The proofs of these theorems will be given in Section 3. For the definitions appear in these theorems, like the sets $V^n$, $V^n_{n+1}$, $n \in \mathbb{N}$, $n \geq 2$, $V^1$ and the dependent radius, see the next subsection. The first and second of our results, consider the system (1.1), with $f$ an odd polynomial of degree $2n+1$, where $n \in \mathbb{N}$, $n \geq 2$.

**Theorem 1.1.** Let $(\lambda_1, \lambda_2, \ldots, \lambda_n) \in V^n$ be such that $(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) \in V^n_{n+1}$, where $\lambda_{n+1}$ is the dependent radius given by (1.6), if $n \in \mathbb{N}$, $n \geq 2$. Then the system (1.1), with $0 < \varepsilon \ll 1$ and

$$f(y) = \frac{\tau}{2}y^{2n+1} + \cdots + \tau(2n - 2k + 3) \cdots (2n + 1)$$

$$\times \left[1 - \frac{1}{2(n+2)} \sum_{i_1=1}^{n+1} \lambda_{i_1} + \frac{1}{4(n+1)(n+2)} \sum_{i_1, i_2=1}^{n+1} \lambda_{i_1} \lambda_{i_2} + \cdots \right.$$  

$$+ \frac{1}{2k(n-k+3) \cdots (n+2)} (-1)^k \sum_{i_1 < \cdots < i_k}^{n+1} \lambda_{i_1} \cdots \lambda_{i_k} \right] y^{2(n-k)+1} \tag{1.3}$$

$$+ \cdots + \tau \left[1 \cdot 3 \cdots (2n+1) \frac{1}{(2n+1)(n+2)!} (-1)^n \prod_{i_1=1}^{n+1} \lambda_{i_1} \right] y,$$

where $\tau \in \mathbb{R} \setminus \{0\}$ and $1 \leq k \leq n-1$, has exactly the following $n+1$ limit cycles:

$$x^2 + y^2 = \lambda_1 + O(\varepsilon), \quad x^2 + y^2 = \lambda_2 + O(\varepsilon), \ldots, \quad x^2 + y^2 = \lambda_{n+1} + O(\varepsilon).$$

Furthermore, (assuming from now on an ordering such that $\lambda_1 < \lambda_2 < \cdots < \lambda_n < \lambda_{n+1}$, where now $\lambda_{n+1}$ is not necessary the dependent radius) we have for the stability of the limit cycles that, if $\tau > 0$ (respectively $\tau < 0$),

$$x^2 + y^2 = \lambda_1 + O(\varepsilon), \quad x^2 + y^2 = \lambda_2 + O(\varepsilon), \ldots, \quad x^2 + y^2 = \lambda_{n+1} + O(\varepsilon)$$

are stable (respectively unstable) and

$$x^2 + y^2 = \lambda_2 + O(\varepsilon), \quad x^2 + y^2 = \lambda_3 + O(\varepsilon), \ldots, \quad x^2 + y^2 = \lambda_n + O(\varepsilon)$$

are unstable (respectively stable) for $n$ even; and

$$x^2 + y^2 = \lambda_1 + O(\varepsilon), \quad x^2 + y^2 = \lambda_3 + O(\varepsilon), \ldots, \quad x^2 + y^2 = \lambda_n + O(\varepsilon)$$

are unstable (respectively stable) for $n$ odd.
are unstable (respectively stable) and
\[ x^2 + y^2 = \lambda_2 + O(\varepsilon), \quad x^2 + y^2 = \lambda_4 + O(\varepsilon), \ldots, \quad x^2 + y^2 = \lambda_{n+1} + O(\varepsilon) \]
are stable (respectively unstable) for \( n \) odd.

**Theorem 1.2.** For system (1.1), where \( \varepsilon \) is small and \( f \) is an arbitrary odd polynomial of degree \( 2n+1 \) we have that the number of \( n+1 \) limit cycles is an upper bound for the number of limit cycles. Moreover, from the set of all the odd polynomials, the polynomials \( f \) given by (1.3), are the only that attain that upper bound.

Our third and fourth results, concern the system (1.1), with \( f \) an odd polynomial of degree 3.

**Theorem 1.3.** Let \( \lambda_1 \in V^1 \). Then the system (1.1), with \( 0 < \varepsilon \ll 1 \) and
\[ f(y) = \tau y^3 - \frac{1}{8} \lambda_1 \lambda_2 y, \] (1.4)
where \( \tau \in \mathbb{R} \setminus \{0\} \) and \( \lambda_2 \) is the dependent radius given by (1.7), has exactly the following 2 limit cycles:
\[ x^2 + y^2 = \lambda_1 + O(\varepsilon), \quad x^2 + y^2 = \lambda_2 + O(\varepsilon). \]
Furthermore, (assuming from now on an ordering such that \( \lambda_1 < \lambda_2 \), where now \( \lambda_2 \) is not necessary the dependent radius) we have for the stability of the limit cycles that, if \( \tau > 0 \) (respectively \( \tau < 0 \)) \( x^2 + y^2 = \lambda_1 + O(\varepsilon) \) is unstable (respectively stable) and \( x^2 + y^2 = \lambda_2 + O(\varepsilon) \) is stable (respectively unstable).

**Theorem 1.4.** For system (1.1), where \( \varepsilon \) is small and \( f \) is an arbitrary odd polynomial of degree 3 we have that the number of 2 limit cycles is an upper bound for the number of limit cycles. Moreover, from the set of all the odd polynomials, the polynomials \( f \) given by (1.4), are the only that attain that upper bound.

**Remark 1.5.** It is important to note that the above theorems don’t inform us which limit cycles we have for a differential equation of the form (1.1). That we succeed through these theorems is to construct differential equations of the form (1.1) with \( n \) given limit cycles and one limit cycle which is close to the circle with the dependent radius, for particularly chosen odd polynomials \( f \) of degree \( 2n+1 \). So, we show how to construct differential equations of the form (1.1) that attain the upper bound of \( n+1 \) limit cycles, when the odd polynomial \( f \) is of degree \( 2n+1 \). Evenly important it is still and one negative result which can be obtained by these theorems, that we know a priori which limit cycles we can’t have for system (1.1) with odd polynomials \( f \) of degree \( 2n+1 \). Substantially, we construct the set of all the possible limiting radii of limit cycles for the system (1.1) with odd polynomials \( f \) of degree \( 2n+1 \). This is the set \( V_{n+1}^n \) which contains the \( \Lambda \)-points (see Definition 1.22).

**Remark 1.6.** It is surprising the connection between the dependent radius for a circle (see Definition 1.13) and the existence of one branch which can not separate from the rest branches for an algebraic curve. More specifically, relatively to the existence of such branch we refer the following of Hilbert’s speech about the first part of Hilbert’s 16th problem “As of the curves of degree 6, I have -admittedly in a rather elaborate way- convinced myself that the 11 branches, that they can have according to Harnack, never all can be separate, rather there must exist one branch, which have another branch running in its interior and nine branches running in its
exterior, or opposite”. Here, we have for the relative positions of limit cycles that
the limit cycle which is close to the circle with the dependent radius can not lie
wherever, contrary the position of this limit cycle depends on the position of the
rest limit cycles. In this sense, we can say that the first and second part of Hilbert’s
16th problem come closer.

**Remark 1.7.** I would mention for system [1.1] that by forcing the coefficients of
an arbitrary odd polynomial to be those given in the Theorem [1.1] when
\( n \in \mathbb{N}, n \geq 2 \) (respectively in the Theorem [1.3] when \( n = 1 \)), do not allow us to put \( n + 1 \)
(respectively 2) limit cycles in arbitrary placements. The reason for this is the
Theorem [1.2] (respectively the Theorem [1.4]); in the statement of these theorems we
see that the proposing polynomials \( f \) (given in Theorems [1.1] and [1.3]) are the only
that attain the upper bound of the \( n + 1 \) limit cycles. Now it is easy to see that
in the coefficients of these polynomials (unless in the first monomial in each case)
appears the dependent radius, and this observation in turn implies that one limit
cycle do not lie in arbitrary placements.

In order to see this more clearly consider for the system (1.1) the case where
\( n = 1 \). Once we chose \( \lambda_1 \) from \( V^1 \), the dependent radius \( \lambda_2 \) follows from (1.7) will
be positive (see Proposition 1.14) and different from the associated \( \lambda_1 \) (see Remark
1.17), and then for the system (1.1) with \( n = 1 \), the polynomial \( f \) given by (1.4) is
the only that realizing the maximal number of 2 limit cycles, and are asymptotic
to the circles \( x^2 + y^2 = \lambda_1 \) and \( x^2 + y^2 = \lambda_2 \) (note that for this circle the placement
is not arbitrary, it depends on \( \lambda_1 \)) as \( \varepsilon \to 0 \) (see Theorems 1.3 and 1.4). (See and
Example 4.7.)

### 1.2. Definitions.
In this subsection, we introduce some new definitions. These
definitions are obtained by using technical integral expressions (see Remark 1.8)
and properties of symmetric functions of the roots of polynomials (Vieta’s formulas).
The first of these definitions has an important role in the construction of the
sinusoidal-type sets and also the advantage played by this definition along with the
Definition [1.11] is going to be understandable in the proof of Proposition 1.14.

**Remark 1.8.** I adopt the sinusoidal terminology for the next two definitions, due
to the formula
\[
\int_0^{2\pi} \sin^{2n} t \, dt = \frac{1 \cdot 3 \cdots (2n - 3)(2n - 1)}{2^{n-1}n!} \pi, \quad \text{for } n \in \mathbb{N},
\]
(see [9]) which gives the coefficients of the sums and products.

**Definition 1.9** (sinusoidal-type numbers). Let \( \lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n \) be distinct pos-
tive real numbers, where \( n \in \mathbb{N}, n \geq 2 \). We define for \( n \in \mathbb{N}, n \geq 3 \), the sinusoidal-
type numbers of order \( n \), associated to the \( \lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n \)
\[
s^n := 2(n + 2) + \cdots + \frac{(-1)^k}{2k-1}(n-k+3)\cdots(n+1) \sum_{i_1,\ldots,i_k=1}^{n} \lambda_{i_1}\cdots\lambda_{i_k} + \cdots
\]
\[
+ \frac{(-1)^n}{2n-2(n+1)!} \prod_{i_1=1}^{n} \lambda_{i_1},
\]
\[
s^n := 2(n + 1) + \cdots + \frac{(-1)^k}{2k-1}(n-k+2)\cdots(n-k+3)\cdots n \sum_{i_1,\ldots,i_k=1}^{n} \lambda_{i_1}\cdots\lambda_{i_k} + \cdots
\]
+ \frac{(-1)^n}{2n-1} \prod_{i_1=1}^{n} \lambda_{i_1},
\tilde{s}^n := \frac{1}{4n(n+1)} \sum_{i_1,i_2=1}^{n} \lambda_{i_1} \lambda_{i_2} + \ldots
+ \frac{(-1)^k(k-1)}{2^k(n-k+2)(n-k+3)\ldots(n+1)} \sum_{i_1,\ldots,i_k=1}^{n} \lambda_{i_1} \ldots \lambda_{i_k} + \ldots
+ \frac{(-1)^n(n-1)}{2^n(n+1)!} \prod_{i_1=1}^{n} \lambda_{i_1},

where 2 \leq k \leq n - 1 for the $\bar{s}^n, \hat{s}^n$ and 3 \leq k \leq n - 1 for $\tilde{s}^n$. In the special case where $n = 2$, we define the sinusoidal-type numbers of second order, associated to the $\lambda_1, \lambda_2$

$\bar{s}^2 := 8 + \frac{1}{6} \lambda_1 \lambda_2,$
$\hat{s}^2 := 6 + \frac{1}{4} \lambda_1 \lambda_2,$
$\tilde{s}^2 := \frac{1}{24} \lambda_1 \lambda_2.$

For $n = 1$, we define the sinusoidal-type numbers of first order

$\bar{s}^1 := 6, \quad \hat{s}^1 := 4.$

For the sinusoidal-type numbers we have the following result. The proof is given in the Appendix.

**Lemma 1.10.** For $n \in \mathbb{N}, n \geq 2$, we have that

$\bar{s}^n = \hat{s}^n \iff \bar{s}^n = 1,$
$\bar{s}^n > \hat{s}^n \iff \bar{s}^n < 1,$
$\bar{s}^n < \hat{s}^n \iff \bar{s}^n > 1,$

where $\bar{s}^n, \hat{s}^n$ and $\tilde{s}^n$ are the sinusoidal-type numbers of order $n$, with $n \in \mathbb{N}, n \geq 2$, of the Definition 1.9.

We continue with another definition. The role played by this definition is that the square roots of the coordinates $\lambda_1, \lambda_2, \ldots, \lambda_n$ of the points $(\lambda_1, \lambda_2, \ldots, \lambda_n)$, where $n \in \mathbb{N}, n \geq 2$, are going to be the limiting radii of the limit cycles which are asymptotic to circles of radii $\sqrt{\lambda_i}$ for $i = 1, 2, \ldots, n$ centered at the origin when the small positive parameter of our system tending to 0. This will be done by forcing $\sqrt{\lambda_1}, \sqrt{\lambda_2}, \ldots, \sqrt{\lambda_n}$ to be simple roots of the polynomial $F$ defined in (2.5) (see Theorem 2.2). For this reason, we assume that the given $\lambda_1, \lambda_2, \ldots, \lambda_n$ are all positive and with $\lambda_i \neq \lambda_j$ for all $i \neq j$ where $i, j = 1, 2, \ldots, n$. In this way, we are going to construct $n$ limit cycles for system (1.1). But Iliev in [4] proved that the maximal number of limit cycles due to polynomial perturbations of degree $n$ of the harmonic oscillator is equal to $\left[ \frac{n-1}{2} \right]$ (the largest integer less than or equal to $\frac{n-1}{2}$). Since in our case the polynomial perturbations are of degree $2n + 3$ we can achieve $n + 1$ limit cycles. Now, we see that we can have an additional limit cycle. About the position of this limit cycle we later give the definition of the dependent radius.
The same observation of all the above is valid and in the case where \( n = 1 \).

**Definition 1.11** (sinusoidal-type sets). For \( n \in \mathbb{N}, n \geq 2 \), we define the sinusoidal-type sets of order \( n \) as

\[
S^n_1 := \left\{ (\lambda_1, \lambda_2, \ldots, \lambda_n) : \lambda_i \neq \lambda_j \forall i \neq j \text{ where } i, j = 1, 2, \ldots, n \text{ with } \lambda_i > 0 \right\},
\]

\[
S^n_2 := \left\{ (\lambda_1, \lambda_2, \ldots, \lambda_n) : \lambda_i \neq \lambda_j \forall i \neq j \text{ where } i, j = 1, 2, \ldots, n \text{ with } \lambda_i > 0 \right\},
\]

\[
S^n_3 := \left\{ (\lambda_1, \lambda_2, \ldots, \lambda_n) : \lambda_i \neq \lambda_j \forall i \neq j \text{ where } i, j = 1, 2, \ldots, n \text{ with } \lambda_i > 0 \right\},
\]

\[
S^n_4 := \left\{ (\lambda_1, \lambda_2, \ldots, \lambda_n) : \lambda_i \neq \lambda_j \forall i \neq j \text{ where } i, j = 1, 2, \ldots, n \text{ with } \lambda_i > 0 \right\},
\]

\[
S^n_5 := \left\{ (\lambda_1, \lambda_2, \ldots, \lambda_n) : \lambda_i \neq \lambda_j \forall i \neq j \text{ where } i, j = 1, 2, \ldots, n \text{ with } \lambda_i > 0 \right\},
\]

\[
S^n_6 := \left\{ (\lambda_1, \lambda_2, \ldots, \lambda_n) : \lambda_i \neq \lambda_j \forall i \neq j \text{ where } i, j = 1, 2, \ldots, n \text{ with } \lambda_i > 0 \right\},
\]

where \( \bar{s}^n, \hat{s}^n \) and \( \tilde{s}^n \) are the sinusoidal-type numbers of order \( n \), with \( n \in \mathbb{N}, n \geq 2 \), of the Definition 1.9. For \( n = 1 \), we define the sinusoidal-type sets of first order

\[
S^1_1 := \{ \lambda_1 : \lambda_1 \in (0, 4) \},
\]

\[
S^1_2 := \{ \lambda_1 : \lambda_1 \in (6, +\infty) \}.
\]

**Definition 1.12.** We define for \( n \in \mathbb{N}, n \geq 2 \), the set \( V^n \) as the set

\[
V^n := \bigcup_{i=1}^6 S^n_i.
\]

For \( n = 1 \), we define the set \( V^1 \) as the set

\[
V^1 := S^1_1 \cup S^1_2.
\]

Now, we continue with the last statement of the observation that we made before the Definition 1.11. The positions of the \( n \) limit cycles have to satisfy an algebraic relation in order that there is an odd polynomial \( f \), realizing the maximal number of limit cycles, and the position of the \((n+1)\)-th limit cycle is estimated in terms of the positions of these \( n \) limit cycles. On this we have the following definition.
Definition 1.13 (dependent radius). Let \((\lambda_1, \lambda_2, \ldots, \lambda_n) \in \mathbb{R}^n, n \in \mathbb{N}, n \geq 2\). We call dependent radius representing with \(\lambda_{n+1}\) the quantity (when is defined) given by the formula

\[
\lambda_{n+1} = \lambda_{n+1}(\lambda_1, \lambda_2, \ldots, \lambda_n) := \frac{\Xi}{\Psi},
\]

where

\[
\Xi = 2^{n+1}(n+2)! + \cdots + (-1)^k 2^{n-k+1}(n-k+2)! \sum_{i_1, \ldots, i_k = 1}^{n} \lambda_{i_1} \cdots \lambda_{i_k}
\]

\[
+ \cdots + 4(-1)^n \prod_{i_1 = 1}^{n} \lambda_{i_1}
\]

and

\[
\Psi = 2^n(n+1)! + \cdots + (-1)^k 2^{n-k}(n-k+1)! \sum_{i_1, \ldots, i_k = 1}^{n} \lambda_{i_1} \cdots \lambda_{i_k}
\]

\[
+ \cdots + (-1)^n \prod_{i_1 = 1}^{n} \lambda_{i_1},
\]

where \(1 \leq k \leq n-1\). So, the dependent radius is the \((n+1)\)-th radius associated to the radii \(\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n\).

For \(n = 1\), let \(\lambda_1 \in \mathbb{R}\), then we call dependent radius representing with \(\lambda_2\) the quantity (when is defined) given by the formula

\[
\lambda_2 = \lambda_2(\lambda_1) := \frac{24 - 4\lambda_1}{4 - \lambda_1}.
\]

So, in this case the dependent radius is the second radius associated to the radius \(\lambda_1\).

For the dependent radius we have the following result. The proof is given in the Appendix.

Proposition 1.14. If \((\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n) \in V^n, n \in \mathbb{N}, n \geq 2\), then the dependent radius \(\lambda_{n+1} = \lambda_{n+1}(\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n), n \in \mathbb{N}, n \geq 2\), is positive. If \(n = 1\) and suppose that \(\lambda_1 \in V^1\), then the dependent radius \(\lambda_2 = \lambda_2(\lambda_1)\) is positive.

On the other hand if \(\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n, n \in \mathbb{N}, n \geq 2\), are distinct positive real numbers so that the dependent radius \(\lambda_{n+1}, n \in \mathbb{N}, n \geq 2\), associated with the radii \(\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n\) is positive, then \((\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n) \in V^n, n \in \mathbb{N}, n \geq 2\). If \(\lambda_1\) is a positive real number so that the dependent radius \(\lambda_2\) associated to the radius \(\lambda_1\) is positive, then \(\lambda_1 \in V^1\).

Remark 1.15. According to Proposition 1.14, the set \(V^n\) is the biggest set from which we can choose the points \((\lambda_1, \lambda_2, \ldots, \lambda_n)\) so that the corresponding dependent radius \(\lambda_{n+1}\) given by \(1.6\), is positive if \(n \in \mathbb{N}, n \geq 2\) and the set \(V^1\) is the biggest set from which we can choose the numbers \(\lambda_1\) so that the corresponding dependent radius \(\lambda_2\) given by \(1.7\), is positive.

Now, is following the definition which has the central role. The advantage played by this definition is that the square roots of the coordinates \(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}\) (where \(\lambda_{n+1}\) is the dependent radius associated to the radii \(\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n\)
of the points \((\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1})\), where \(n \in \mathbb{N}, n \geq 2\), are going to be the limiting radii of the limit cycles which are asymptotic to circles of radii \(\sqrt{X_i}\) for \(i = 1, 2, \ldots, n, n+1\) centered at the origin when the small positive parameter of our system tending to 0. This will be done by forcing \(\sqrt{X_1}, \sqrt{X_2}, \ldots, \sqrt{X_n}, \sqrt{X_{n+1}}\) to be all the simple roots of the polynomial \(F\) defined in (2.5) (see Theorem 2.2). For this reason, we assume that the given points \((\lambda_1, \lambda_2, \ldots, \lambda_n)\) belong to \(V^n\) and we want for the corresponding dependent radius \(\lambda_{n+1} = \lambda_{n+1}(\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n)\) (which from Proposition 1.14 is positive) to satisfy that \(\lambda_{n+1} \neq \lambda_j\) for all \(j = 1, 2, \ldots, n\). In this way, we construct \(n + 1\) limit cycles due to polynomial perturbations of degree \(2n + 3\) of the harmonic oscillator (see §).

The same observation of all the above is valid and in the case where \(n = 1\).

**Definition 1.16.** We define now for \(n \in \mathbb{N}, n \geq 2\), the sets

\[
S^n_{1,n+1} := \{(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) : (\lambda_1, \lambda_2, \ldots, \lambda_n) \in S^n_1, \lambda_{n+1} = \lambda_{n+1}(\lambda_1, \ldots, \lambda_n), \\
\lambda_{n+1} \neq \lambda_j \forall j = 1, 2, \ldots, n\},
\]

\[
S^n_{2,n+1} := \{(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) : (\lambda_1, \lambda_2, \ldots, \lambda_n) \in S^n_2, \lambda_{n+1} = \lambda_{n+1}(\lambda_1, \ldots, \lambda_n), \\
\lambda_{n+1} \neq \lambda_j \forall j = 1, 2, \ldots, n\},
\]

\[
S^n_{3,n+1} := \{(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) : (\lambda_1, \lambda_2, \ldots, \lambda_n) \in S^n_3, \lambda_{n+1} = \lambda_{n+1}(\lambda_1, \ldots, \lambda_n), \\
\lambda_{n+1} \neq \lambda_j \forall j = 1, 2, \ldots, n\},
\]

\[
S^n_{4,n+1} := \{(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) : (\lambda_1, \lambda_2, \ldots, \lambda_n) \in S^n_4, \lambda_{n+1} = \lambda_{n+1}(\lambda_1, \ldots, \lambda_n), \\
\lambda_{n+1} \neq \lambda_j \forall j = 1, 2, \ldots, n\},
\]

\[
S^n_{5,n+1} := \{(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) : (\lambda_1, \lambda_2, \ldots, \lambda_n) \in S^n_5, \lambda_{n+1} = \lambda_{n+1}(\lambda_1, \ldots, \lambda_n), \\
\lambda_{n+1} \neq \lambda_j \forall j = 1, 2, \ldots, n\},
\]

\[
S^n_{6,n+1} := \{(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) : (\lambda_1, \lambda_2, \ldots, \lambda_n) \in S^n_6, \lambda_{n+1} = \lambda_{n+1}(\lambda_1, \ldots, \lambda_n), \\
\lambda_{n+1} \neq \lambda_j \forall j = 1, 2, \ldots, n\},
\]

where \(S^n_1, S^n_2, S^n_3, S^n_4, S^n_5, S^n_6\) and \(S^n_0\) are the sinusoidal-type sets of order \(n\), with \(n \in \mathbb{N}, n \geq 2\), of the Definition 1.11 and \(\lambda_{n+1}\) is the dependent radius given by (1.6). For \(n = 1\), we define the sets

\[
S^1_{1,2} := \{(\lambda_1, \lambda_2) : \lambda_1 \in S^1_1, \lambda_2 = \lambda_2(\lambda_1), \lambda_2 \neq \lambda_1\},
\]

\[
S^1_{2,2} := \{(\lambda_1, \lambda_2) : \lambda_1 \in S^1_2, \lambda_2 = \lambda_2(\lambda_1), \lambda_2 \neq \lambda_1\},
\]

where \(S^1_1\) and \(S^1_2\) are the sinusoidal-type sets of first order of the Definition 1.11 and \(\lambda_2\) is the dependent radius given by (1.7).

**Remark 1.17.** Notice that, if \(\lambda_1 \in (0, 4)\), then the dependent radius \(\lambda_2\) given by (1.7), belongs to \((6, +\infty)\) and so we have that \((\lambda_1, \lambda_2) \in S^n_{1,2}\). If \(\lambda_1 \in (6, +\infty)\), then the dependent radius \(\lambda_2\) given by (1.7), belongs to \((0, 4)\) and so we have that \((\lambda_1, \lambda_2) \in S^n_{2,2}\).

**Remark 1.18.** According to Remark 1.17 the sets \(S^1_{1,2}\) and \(S^1_{2,2}\), which defined as above, take the more simple form

\[
S^1_{1,2} = \{(\lambda_1, \lambda_2) : \lambda_1 \in S^1_1, \lambda_2 = \lambda_2(\lambda_1)\},
\]

\[
S^1_{2,2} = \{(\lambda_1, \lambda_2) : \lambda_1 \in S^1_2, \lambda_2 = \lambda_2(\lambda_1)\},
\]
where $S^1_1$ and $S^1_2$ are the sinusoidal-type sets of first order of the Definition 1.11 and $\lambda_2$ is the dependent radius given by (1.7).

**Definition 1.19.** We define for $n \in \mathbb{N}, n \geq 2$, the set $V^n_{n+1}$ as the set

$$V^n_{n+1} := \bigcup_{i=1}^{6} S^i_{1,n+1}.$$

For $n = 1$, we define the set $V^1_2$ as the set

$$V^1_2 := S^1_{1,1} \cup S^1_{2,2}.$$

**Remark 1.20.** In the set $V^n_{n+1}, n \in \mathbb{N}$, the positive dependent radius $\lambda_{n+1}, n \in \mathbb{N}$, is obviously different from $\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n, n \in \mathbb{N}$.

**Remark 1.21.** It is possible, for $n \in \mathbb{N}, n \geq 2$, the point $(\lambda_1, \lambda_2, \ldots, \lambda_n) \in V^n$ but the point $(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) \notin V^n_{n+1}$, where $\lambda_{n+1}$ is the dependent radius given by (1.6), associated to the radii $\lambda_1, \lambda_2, \ldots, \lambda_n$. (For example, it is easy to see that the point $(4, 6) \in V^2$; in particular belongs to $S^2_3$. We calculate the dependent radius $\lambda_3$, associated to the 4, 6, which from Proposition 1.14 is positive and we have that $\lambda_3 = 6$. Now, the point $(4, 6, 6) \notin V^2_2$.)

For $n = 1$, according to Remark 1.17 if $\lambda_1 \in V^1$, then $(\lambda_1, \lambda_2) \in V^1_2$, where $\lambda_2$ is the dependent radius given by (1.7), associated to the radius $\lambda_1$.

**Definition 1.22** (A-points (lambda points)). We will call the points

$$(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) \in V^n_{n+1}, \ n \in \mathbb{N},$$

the A-points.

1.3. Known results on Liénard equations. We now continue with known results on Liénard equations. Such equations are very challenging and many questions about these are still open. Note that Smale [11] proposed to study Hilbert’s 16th problem restricted to these special classes. This is Smale’s 13th problem. We mention several interesting works here. The Liénard equation

$$\ddot{x} + g(x)\dot{x} + x = 0,$$  

(1.8)

where $g$ is a polynomial, is another generalization of the Van der Pol equation. Equation (1.8) can be studied in a phase plane as a system

$$\dot{x} = y,$$

$$\dot{y} = -x - g(x)y,$$

(1.9)

or in the so-called Liénard plane as

$$\dot{x} = y - G(x),$$

$$\dot{y} = -x,$$  

(1.10)

where $G(x) = \int_0^x g(s)\,ds$. The systems (1.9) and (1.10) are analytically conjugate. We observe that system (1.1) is not of the form of Liénard’s equation (1.9), except when $f(y) = y$. Obviously, for $f(y) \neq y$, (1.9) can not reduce to (1.1). So, in general, (1.1) is not a special case of (1.9) and (1.9) is not a special case of (1.1).

Liénard [6] proved that, if $G$ is a continuous odd function, which has a unique positive root at $x = a$ and is monotone increasing for $x \geq a$, then (1.10) has a unique limit cycle. Rychkov [10] proved that, if $G$ is an odd polynomial of degree 5, then (1.10) has at most two limit cycles.

Lins, de Melo and Pugh [7] have studied the Liénard equation (1.10), where $G$ is a polynomial of degree $d$. They proved that, if $G(x) = a_3 x^3 + a_2 x^2 + a_1 x$, then
system (1.10) has at most one limit cycle. In fact, they gave a complete classification of
the phase space of the cubic Liénard’s equation, in terms of some explicit algebraic
conditions on the coefficients of $G$. Also, using a method due to Poincaré they
proved that, if $d = 2n + 1$ or $2n + 2$, then for any $k \in \mathbb{N}_0$ with $0 \leq k \leq n$ there
exists a polynomial $G(x) = a_dx^d + \cdots + a_1x$ such that the system (1.10) has exactly
$k$ closed orbits. Motivated by this, they conjectured that the maximum number of
limit cycles for system (1.10), where $G$ is a polynomial of degree $n$ would be equal
to $\left\lfloor \frac{n-1}{2} \right\rfloor$.

However, in [3] it has been proven by Dumortier, Panazzolo and Roussarie the
existence of classical Liénard equations (1.10) of degree 7 with at least 4 limit cycles.
This easily implied the existence of classical Liénard equations of degree $n$, $n \geq 7$,
with $\left\lfloor \frac{n-1}{2} \right\rfloor + 1$ limit cycles. The counterexamples were proven to occur in systems

\[
\begin{align*}
\dot{x} &= y - \left(x^7 + \sum_{i=2}^{6} c_i x^i \right), \\
\dot{y} &= \varepsilon(b - x),
\end{align*}
\]

for small $\varepsilon > 0$. Recently, in [8] it has been proven by De Maesschalck and Dumortier the
existence of classical Liénard equations (1.10) of degree 6 having 4 limit cycles. It implies the existence of classical Liénard equations of degree $n$, $n \geq 6$,
having at least $\left\lfloor \frac{n-1}{2} \right\rfloor + 2$ limit cycles.

Ilyashenko and Panov [5] proved that, if

\[
G(x) = x^n + \sum_{i=1}^{n-1} a_i x^i, \quad |a_i| \leq C, \quad C \geq 4, \quad n \geq 5,
\]

and suppose that $n$ is odd, then the number $L(n, C)$ of limit cycles of (1.10) admits
the upper estimate

\[
L(n, C) \leq \exp(\exp C^{14n}).
\]

Caubergh and Dumortier [2] proved that the maximal number of limit cycles for
system (1.10) of even degree is finite when restricting the coefficients to a compact, thus
proving the existential part of Hilbert’s 16th problem for Liénard equations when
restricting the coefficients to a compact set.

2. Elementary remarks about small perturbation of a Hamiltonian system

We consider the system

\[
\begin{align*}
\dot{x} &= y + \varepsilon f_1(x, y), \\
\dot{y} &= -x + \varepsilon f_2(x, y),
\end{align*}
\]

where $0 < \varepsilon \ll 1$ and $f_1$, $f_2$ are $C^1$ functions of $x$ and $y$, which is a perturbation of
the linear harmonic oscillator

\[
\begin{align*}
\dot{x} &= y, \\
\dot{y} &= -x,
\end{align*}
\]

which has all the solutions periodic with:

\[
x^0(t) = A \cos(t - t_0) \quad \text{and} \quad y^0(t) = -A \sin(t - t_0).
\]

In general, the phase curves of (2.1) are not closed and it is possible to have
the form of a spiral with a small distance of order $\varepsilon$ between neighboring turns.
In order to decide if the phase curve approaches the origin or recedes from it, we consider the function (mechanic energy)

\[ E(x, y) = \frac{1}{2}(x^2 + y^2). \]

It is easy to compute the derivative of the energy and it is proportional to \( \varepsilon \):

\[ \frac{d}{dt}E(x, y) = \dot{x}\dot{x} + \dot{y}\dot{y} = \varepsilon \left(x f_1(x, y) + y f_2(x, y)\right) =: \varepsilon \dot{E}(x, y). \tag{2.2} \]

We want information for the sign of the quantity

\[ \int_0^{T(\varepsilon)} \varepsilon \dot{E}(x^\varepsilon(t), y^\varepsilon(t)) dt =: \Delta E, \tag{2.3} \]

which corresponds to the change of energy of \((x^\varepsilon(t), y^\varepsilon(t))\) in one complete turn:

\[ y^\varepsilon(0) = y^\varepsilon(T(\varepsilon)) = 0. \]

Using the theorem of continuous dependence on parameters in ODEs, one can prove the following lemma (see [1]):

**Lemma 2.1.** For (2.3) we have

\[ \Delta E = \varepsilon \left[ F(A) + \frac{o(\varepsilon)}{\varepsilon} \right]. \tag{2.4} \]

Let

\[ F(A) := \int_0^{2\pi} \dot{E}(x^0(t), y^0(t)) dt, \tag{2.5} \]

and we write (2.4) as

\[ \Delta E = \varepsilon \left[ F(A) + \frac{o(\varepsilon)}{\varepsilon} \right]. \]

Using the implicit function theorem, one can prove the following theorem, which is the Poincaré’s method (see [1]):

**Theorem 2.2.** If the function \( F \) given by (2.5), has a positive simple root \( A_0 \), namely

\[ F(A_0) = 0 \quad \text{and} \quad F'(A_0) \neq 0, \]

then \((2.1)\) has a periodic solution with amplitude \( A_0 + O(\varepsilon) \) for \( 0 < \varepsilon \ll 1. \)

3. PROOFS OF THEOREMS 1.1 1.2 1.3 AND 1.4

**Proof of Theorem 1.1** From (2.2) we have

\[ \dot{E}(x, y) = y f(y)(1 - x^2), \tag{3.1} \]

where \( f \) is the polynomial introduced in (1.3). Substituting (3.1) into (2.5), we obtain that

\[ F(A) = \int_0^{2\pi} y^0(t) f(y^0(t)) \left(1 - (x^0(t))^2\right) dt, \tag{3.2} \]

where \( f \) is the polynomial introduced in (1.3). We insert the definition of \( f \) given by (1.3) in (3.2) to obtain

\[ F(A) = \tau \int_0^{2\pi} \left[(y^0(t))^{2(n+1)} + (2n + 1) \left(1 - \frac{1}{2(n+2)} \sum_{i=1}^{n+1} \lambda_i\right)(y^0(t))^{2n} \right. \]

\[ + \cdots + \left(\frac{1 \cdot 3 \cdots (2n + 1)}{2^{n+1}(n+2)!} (-1)^n \prod_{i=1}^{n+1} \lambda_i\right)(y^0(t))^2 \left(1 - (x^0(t))^2\right) dt. \tag{3.3} \]
Substituting $x^0(t) = A \cos(t - t_0)$ and $y^0(t) = -A \sin(t - t_0)$ into (3.3) we get

\[
F(A) = \pi A^2 \int_0^{2\pi} \left[ A^{2n} \sin^{2(n+1)}(t - t_0) 
+ (2n + 1) \left( 1 - \frac{1}{2(n+2)} \sum_{i_1=1}^{n+1} \lambda_{i_1} \right) A^{2(n-1)} \sin^{2n}(t - t_0) 
+ \cdots + \left( \frac{1 \cdot 3 \cdots (2n + 1)}{2^{n+1} (n+2)!} (-1)^n \prod_{i_1=1}^{n+1} \lambda_{i_1} \right) \sin^2(t - t_0) \right] 
\times \left[ 1 - A^2 + A^2 \sin^2(t - t_0) \right] dt,
\]

whence, after multiplying the terms in the two brackets we get

\[
F(A) = \pi A^2 \int_0^{2\pi} \left[ A^{2n} \sin^{2(n+1)}(t - t_0) - A^{2(n+1)} \sin^{2(n+1)}(t - t_0) 
+ A^{2(n+1)} \sin^{2(n+2)}(t - t_0) 
+ (2n + 1) \left( 1 - \frac{1}{2(n+2)} \sum_{i_1=1}^{n+1} \lambda_{i_1} \right) A^{2(n-1)} \sin^{2n}(t - t_0) 
- (2n + 1) \left( 1 - \frac{1}{2(n+2)} \sum_{i_1=1}^{n+1} \lambda_{i_1} \right) A^{2n} \sin^2(t - t_0) 
+ (2n + 1) \left( 1 - \frac{1}{2(n+2)} \sum_{i_1=1}^{n+1} \lambda_{i_1} \right) A^{2(n+1)} \sin^2(t - t_0) 
+ \cdots + \left( \frac{1 \cdot 3 \cdots (2n + 1)}{2^{n+1} (n+2)!} (-1)^n \prod_{i_1=1}^{n+1} \lambda_{i_1} \right) \sin^2(t - t_0) \right] 
\times \left[ 1 - A^2 + A^2 \sin^2(t - t_0) \right] dt.
\]

Using now (4.5), we finally obtain

\[
F(A) = \pi \tau A^2 \frac{1 \cdot 3 \cdots (2n + 1)}{2^{n+1} (n+2)!} \left[ - A^{2(n+1)} + \sum_{i_1=1}^{n+1} \lambda_{i_1} A^{2n} - \sum_{i_1,i_2=1}^{n+1} \lambda_{i_1} \lambda_{i_2} A^{2(n-1)} 
+ \cdots + (-1)^k \sum_{i_1,\ldots,i_k=1}^{n+1} \lambda_{i_1} \cdots \lambda_{i_k} A^{2(n-k+1)} - \cdots 
- (-1)^n \sum_{i_1,\ldots,i_n=1}^{n+1} \lambda_{i_1} \cdots \lambda_{i_n} A^2 + (-1)^n \prod_{i_1=1}^{n+1} \lambda_{i_1} \right].
\]
We show now that $\sqrt{\lambda_1}, \sqrt{\lambda_2}, \ldots, \sqrt{\lambda_n}, \sqrt{\lambda_{n+1}}$ are roots of the polynomial $F$. Let

$$W(A) := A^{2(n+1)} - \sum_{i_1=1}^{n+1} \lambda_{i_1} A^{2n} + \sum_{i_1, i_2=1}^{n+1, n+1} \lambda_{i_1} \lambda_{i_2} A^{2(n-1)} - \ldots$$

$$+ (-1)^n \sum_{i_1, \ldots, i_n=1}^{n+1} \lambda_{i_1} \ldots \lambda_{i_n} A^2 - (-1)^n \prod_{i_1=1}^{n+1} \lambda_{i_1},$$

namely, we write

$$F(A) = -\pi A^2 \frac{1 \cdot 3 \cdot \ldots (2n+1)}{2^{n+1}(n+2)!} \cdot W(A).$$

Now, it suffices to show that $\sqrt{\lambda_1}, \sqrt{\lambda_2}, \ldots, \sqrt{\lambda_n}, \sqrt{\lambda_{n+1}}$ are roots of the polynomial $W$. Without loss of generality we consider the quantity $\sqrt{\lambda_1}$. For $W(\sqrt{\lambda_1})$ we have

$$W(\sqrt{\lambda_1}) = \lambda_1^{n+1} - \lambda_1^n \sum_{i_1=1}^{n+1} \lambda_{i_1} + \lambda_1^{n-1} \sum_{i_1, i_2=1}^{n+1, n+1} \lambda_{i_1} \lambda_{i_2} - \ldots - (-1)^n \prod_{i_1=1}^{n+1} \lambda_{i_1}$$

$$= \lambda_1^{n+1} - \lambda_1^n - \lambda_1^n \sum_{i_1=2}^{n+1} \lambda_{i_1} + \lambda_1^{n-1} \sum_{i_1=2}^{n+1} \lambda_{i_1} \lambda_{i_2}$$

$$- \lambda_1^{n-1} \sum_{i_1, i_2=2}^{n+1} \lambda_{i_1} \lambda_{i_2} - \lambda_1^{n-2} \sum_{i_1, i_2, i_3=2}^{n+1} \lambda_{i_1} \lambda_{i_2} \lambda_{i_3}$$

$$+ \lambda_1^{n-2} \sum_{i_1, i_2, i_3=2}^{n+1} \lambda_{i_1} \lambda_{i_2} \lambda_{i_3} + \ldots + (-1)^n \prod_{i_1=1}^{n+1} \lambda_{i_1} - (-1)^n \prod_{i_1=1}^{n+1} \lambda_{i_1}$$

$$= 0.$$

So, $\sqrt{\lambda_1}, \sqrt{\lambda_2}, \ldots, \sqrt{\lambda_n}, \sqrt{\lambda_{n+1}}$ are roots of the polynomial $W$ and therefore and for the polynomial $F$.

Now, using Theorem 2.2, it suffices to show that $\sqrt{\lambda_1}, \sqrt{\lambda_2}, \ldots, \sqrt{\lambda_n}, \sqrt{\lambda_{n+1}}$ are not roots of the polynomial $W'$; therefore they are not roots and for polynomial $F'$. For the derivative of $W$ we have that

$$W'(A) = 2A[(n+1)A^{2n} - n \sum_{i_1=1}^{n+1} \lambda_{i_1} A^{2(n-1)} + (n-1) \sum_{i_1, i_2=1}^{n+1, n+1} \lambda_{i_1} \lambda_{i_2} A^{2(n-2)}$$

$$- \ldots - (-1)^n \sum_{i_1, \ldots, i_n=1}^{n+1} \lambda_{i_1} \ldots \lambda_{i_n}].$$

Now, we have that one root of $W'$ is $A = 0$ and we also have another $2n$ roots. From those $2n$ roots, $n$ are positive and the other $n$ are negative (these roots are
opposite numbers). Let
\[ G(A) := (n + 1)A^{2n} - n \sum_{i_1 = 1}^{n+1} \lambda_{i_1} A^{2(n-1)} + (n - 1) \sum_{i_1, i_2 = 1}^{n+1} \lambda_{i_1} \lambda_{i_2} A^{2(n-2)} \]
\[ - \cdots + (-1)^n \sum_{i_1, \ldots, i_n = 1}^{n+1} \lambda_{i_1} \cdots \lambda_{i_n}, \]
namely, we write
\[ W'(A) = 2A \cdot G(A). \]
Now, we check if the roots \( \sqrt{\lambda_1}, \sqrt{\lambda_2}, \ldots, \sqrt{\lambda_n}, \sqrt{\lambda_{n+1}} \) of the polynomial \( W \) are possible to be roots and for the polynomial \( W' \), therefore and for the polynomial \( G \). Without loss of generality we consider the root \( \sqrt{\lambda_1} \) of \( W \). For \( G(\sqrt{\lambda_1}) \) we have
\[ G(\sqrt{\lambda_1}) = (n + 1)\lambda_1^n - n\lambda_1^{n-1} \sum_{i_1 = 1}^{n+1} \lambda_{i_1} + (n - 1)\lambda_1^{n-2} \sum_{i_1, i_2 = 1}^{n+1} \lambda_{i_1} \lambda_{i_2} \]
\[ - \cdots + (-1)^n \sum_{i_1, \ldots, i_n = 1}^{n+1} \lambda_{i_1} \cdots \lambda_{i_n} \]
\[ = \lambda_1^n - \lambda_1^{n-1} \sum_{i_1 = 2}^{n+1} \lambda_{i_2} + \lambda_1^{n-2} \sum_{i_1, i_2 = 2}^{n+1} \lambda_{i_1} \lambda_{i_2} - \lambda_1^{n-3} \sum_{i_1, i_2, i_3 = 2}^{n+1} \lambda_{i_1} \lambda_{i_2} \lambda_{i_3} \]
\[ + \cdots + (-1)^n \lambda_1 \sum_{i_1, \ldots, i_n = 2}^{n+1} \lambda_{i_1} \cdots \lambda_{i_n} + (-1)^n \lambda_2 \lambda_3 \cdots \lambda_n \lambda_{n+1} \]
\[ = (\lambda_1 - \lambda_2)(\lambda_1 - \lambda_3) \cdots (\lambda_1 - \lambda_n)(\lambda_1 - \lambda_{n+1}). \]
Obviously, \( W'(\sqrt{\lambda_1}) \) is not zero since in the set \( V_{n+1} \) we have that \( \lambda_1 \neq \lambda_j \) for \( j = 2, 3, \ldots, n, n+1 \). Similarly, none of the \( \sqrt{\lambda_2}, \sqrt{\lambda_3}, \ldots, \sqrt{\lambda_n}, \sqrt{\lambda_{n+1}} \) is a root of \( W' \).
Therefore, we have that the roots \( \sqrt{\lambda_1}, \sqrt{\lambda_2}, \ldots, \sqrt{\lambda_n}, \sqrt{\lambda_{n+1}} \) of \( W \) are not roots of \( W' \). Finally, none of the roots \( \sqrt{\lambda_1}, \sqrt{\lambda_2}, \ldots, \sqrt{\lambda_n}, \sqrt{\lambda_{n+1}} \) of \( F \) is a root of \( F' \). That is essential so that the \( n + 1 \) simple roots of \( F \) create \( n + 1 \) limit cycles. Hence, from Poincaré’s method (see Theorem 2.2) it follows that \( (1.1) \), with \( f \) be the polynomial introduced in \( (1.3) \), has at least \( n + 1 \) limit cycles, and are asymptotic to circles of radius \( \sqrt{\lambda_i} \) for \( i = 1, 2, \ldots, n + 1 \) centered at the origin as \( \varepsilon \to 0 \).
Let now prove that the number of limit cycles for system \((1.1)\), with \( \varepsilon \) small and \( f \) be the polynomial introduced in \((1.3)\), is exactly \( n + 1 \). The proof of this can be derived from the work of Iliev [4] since it constitutes a special case of the Theorem 1 proved there. Actually, applying this theorem from [4] for the special case \( k = 1 \), since the degree of \((1.1)\) is \( 2n + 3 \) we can obtain at most \( n + 1 \) limit cycles. Finally, combining this result with the result that \((1.1)\), with \( f \) be the polynomial introduced in \((1.3)\), has at least \( n + 1 \) limit cycles we get the desired result, namely that the number of limit cycles for system \((1.1)\), with \( \varepsilon \) small and \( f \) be the polynomial introduced in \((1.3)\) is exactly \( n + 1 \).
Now, concerning the stability of the limit cycles we have the following.
From now on we will suppose for the coordinates $\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}$ of the points $(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) \in V^n_{n+1}, n \in \mathbb{N}, n \geq 2$, an ordering such that $\lambda_1 < \lambda_2 < \cdots < \lambda_n < \lambda_{n+1}$. We can always achieve this since the positive real numbers $\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}$ are distinct. Note that in this order with $\lambda_{n+1}$ we do not necessarily mean the dependent radius. Since

$$G(\sqrt{\lambda_1}) = (\lambda_1 - \lambda_2)(\lambda_1 - \lambda_3) \cdots (\lambda_1 - \lambda_n)(\lambda_1 - \lambda_{n+1}),$$

we have that $W'(\sqrt{\lambda_1}) < 0$ if $n$ is odd and that $W'(\sqrt{\lambda_1}) > 0$ if $n$ is even.

So using the fact that, if $F'(\sqrt{\lambda_i}) < 0$ the limit cycle $x^2 + y^2 = \lambda_i + O(\varepsilon)$ is stable and if $F'(\sqrt{\lambda_i}) > 0$ the limit cycle is unstable we have for the stability of the $n + 1$ limit cycles that, if $\tau > 0$ (respectively $\tau < 0$)

$$x^2 + y^2 = \lambda_1 + O(\varepsilon), \quad x^2 + y^2 = \lambda_3 + O(\varepsilon), \ldots, \quad x^2 + y^2 = \lambda_{n+1} + O(\varepsilon)$$

are stable (respectively unstable) and

$$x^2 + y^2 = \lambda_2 + O(\varepsilon), \quad x^2 + y^2 = \lambda_4 + O(\varepsilon), \ldots, \quad x^2 + y^2 = \lambda_n + O(\varepsilon)$$

are unstable (respectively stable) for $n$ even; and

$$x^2 + y^2 = \lambda_1 + O(\varepsilon), \quad x^2 + y^2 = \lambda_3 + O(\varepsilon), \ldots, \quad x^2 + y^2 = \lambda_{n+1} + O(\varepsilon)$$

are unstable (respectively stable) and

$$x^2 + y^2 = \lambda_2 + O(\varepsilon), \quad x^2 + y^2 = \lambda_4 + O(\varepsilon), \ldots, \quad x^2 + y^2 = \lambda_n + O(\varepsilon)$$

are stable (respectively unstable) for $n$ odd. The proof is complete. \qed

**Proof of Theorem 1.2.** As we already saw, according to Theorem 1 from [4], the number of $n + 1$ limit cycles is an upper bound for the number of limit cycles for system (1.1), where $\varepsilon$ is small and $f$ is an arbitrary odd polynomial of degree $2n + 1$.

Now, it is easy to see that for system (1.1), where $f$ is an arbitrary odd polynomial of degree $2n + 1$, the associated $F$ given by (2.5) is an even polynomial of degree $2n + 4$, with 0 as a double root. Therefore, in general the polynomial $F$ has at most $n + 1$ simple positive roots. Furthermore, since $V^n, n \in \mathbb{N}, n \geq 2$ is the biggest set from which we can choose the points $(\lambda_1, \lambda_2, \ldots, \lambda_n)$ so that the dependent radius $\lambda_{n+1}$ given by (1.6), is positive if $n \in \mathbb{N}, n \geq 2$ (see Remark 1.15) and $F$ as we showed has at most $n + 1$ simple positive roots, we must choose the points $(\lambda_1, \lambda_2, \ldots, \lambda_n, \lambda_{n+1}) \in V^n_{n+1}$, in order the polynomial $F$ has exactly $n + 1$ simple positive roots, and thus, from the set of all the odd polynomials, the polynomials $f$ given by (1.3) are the only such that the system (1.1) attains the upper bound of the $n + 1$ limit cycles. The proof is complete. \qed

**Proof of Theorem 1.3.** The proof is identical as in Theorem 1.1, the only modification is that the polynomial $f$ given by (1.3) will be replaced by the polynomial $f$ introduced in (1.4). \qed

**Proof of Theorem 1.4.** The proof is identical as in Theorem 1.2, the only modification is that the case where $n \in \mathbb{N}, n \geq 2$ will be replaced by $n = 1$. \qed
4. Examples

In this section we illustrate the general theory of this work by some examples.

**Example 4.1.** We consider $\lambda_1 = 4, \lambda_2 = 5$. These $\lambda_1, \lambda_2$ are distinct and positive. We have according to Definition 1.9 that the sinusoidal-type numbers of second order, associated to the values 4, 5 are

$$s^2 := 8 + \frac{1}{6} \lambda_1 \lambda_2 = 8 + \frac{1}{6} \cdot 4 \cdot 5 = \frac{34}{3},$$

$$\tilde{s}^2 := 6 + \frac{1}{4} \lambda_1 \lambda_2 = 6 + \frac{1}{4} \cdot 4 \cdot 5 = 11,$$

$$\tilde{s}^2 := \frac{1}{24} \lambda_1 \lambda_2 = \frac{1}{24} \cdot 4 \cdot 5 = \frac{5}{6}.$$

Since $\lambda_1 + \lambda_2 = 4 + 5 = 9$, we have that $(4, 5) \in S_2^1$ and therefore $(4, 5) \in V^2$. We calculate the dependent radius $\lambda_3$, associated to the values 4, 5, which from Proposition 1.14 is positive and we have that

$$\lambda_3 := \frac{192 - 24(\lambda_1 + \lambda_2) + 4\lambda_1 \lambda_2}{24 - 4(\lambda_1 + \lambda_2) + \lambda_1 \lambda_2} = \frac{192 - 216 + 80}{24 - 36 + 20} = 7.$$

So, we have the A-point $(4, 5, 7)$ which belongs to the set $V_3^2$.

Now, using Theorem 1.11 for $\tau = 16$, we have that the system

$$\dot{x} = y,$$

$$\dot{y} = -x + \varepsilon(16y^5 - 80y^3 + 175y)(1 - x^2), \quad (4.1)$$

with $0 < \varepsilon \ll 1$ has exactly, the limit cycles $x^2 + y^2 = 4 + O(\varepsilon)$, $x^2 + y^2 = 5 + O(\varepsilon)$ and $x^2 + y^2 = 7 + O(\varepsilon)$.

Since $4 < 5 < 7$, the limit cycles $x^2 + y^2 = 4 + O(\varepsilon)$, $x^2 + y^2 = 5 + O(\varepsilon)$ are stable and the limit cycle $x^2 + y^2 = 7 + O(\varepsilon)$ is unstable.

From Theorem 1.11 we have for the system (4.1) that, if we change $\tau$ from 16 to $-16$ the unstable limit cycle $x^2 + y^2 = 7 + O(\varepsilon)$ becomes stable and the stable limit cycles $x^2 + y^2 = 4 + O(\varepsilon)$, $x^2 + y^2 = 5 + O(\varepsilon)$ become unstable.

**Example 4.2.** We consider $\lambda_1 = 4, \lambda_2 = 16$. These $\lambda_1, \lambda_2$ are distinct and positive. We have according to Definition 1.9 that the sinusoidal-type numbers of second order, associated to the values 4, 16 are

$$s^2 := 8 + \frac{1}{6} \lambda_1 \lambda_2 = 8 + \frac{1}{6} \cdot 4 \cdot 16 = \frac{56}{3},$$

$$\tilde{s}^2 := 6 + \frac{1}{4} \lambda_1 \lambda_2 = 6 + \frac{1}{4} \cdot 4 \cdot 16 = 22,$$

$$\tilde{s}^2 := \frac{1}{24} \lambda_1 \lambda_2 = \frac{1}{24} \cdot 4 \cdot 16 = \frac{8}{3}.$$

Since $\lambda_1 + \lambda_2 = 4 + 16 = 20$, we have that $(4, 16) \notin S_2^1$, $(4, 16) \notin S_5^2$ and therefore $(4, 16) \notin V^2$. Therefore from Proposition 1.14 the dependent radius $\lambda_3$, associated to the 4, 16 is not positive.

So, according to the Theorem 1.11 it does not exist a system of the form

$$\dot{x} = y,$$

$$\dot{y} = -x + \varepsilon(a_0 y^5 + a_1 y^3 + a_2 y)(1 - x^2),$$

where $0 < \varepsilon \ll 1$ and $a_0, a_1, a_2 \in \mathbb{R}$, which has exactly three limit cycles whereof the two of them have the equations $x^2 + y^2 = 4 + O(\varepsilon)$, $x^2 + y^2 = 16 + O(\varepsilon)$. 

Example 4.3. We consider \( \lambda_1 = 1, \lambda_2 = 2, \lambda_3 = 3 \). These \( \lambda_1, \lambda_2, \lambda_3 \) satisfy our assertions, since \( \lambda_i \neq \lambda_j \) for all \( i \neq j \) where \( i, j = 1, 2, 3 \) and are positive. We have according to Definition 1.9 that the sinusoidal-type numbers of third order, associated to the 1,2,3 are

\[
\begin{align*}
\bar{s}^3 & := 10 + \frac{1}{8} (\lambda_1 \lambda_2 + \lambda_1 \lambda_3 + \lambda_2 \lambda_3) - \frac{1}{48} \lambda_1 \lambda_2 \lambda_3 = 10 + \frac{11}{8} - \frac{1}{8} = \frac{45}{4}, \\
\hat{s}^3 & := 8 + \frac{1}{6} (\lambda_1 \lambda_2 + \lambda_1 \lambda_3 + \lambda_2 \lambda_3) - \frac{1}{24} \lambda_1 \lambda_2 \lambda_3 = 8 + \frac{11}{6} - \frac{1}{4} = \frac{115}{12}, \\
\check{s}^3 & := \frac{1}{48} (\lambda_1 \lambda_2 + \lambda_1 \lambda_3 + \lambda_2 \lambda_3) - \frac{1}{96} \lambda_1 \lambda_2 \lambda_3 = \frac{11}{48} - \frac{1}{16} = \frac{1}{6}.
\end{align*}
\]

Since \( \lambda_1 + \lambda_2 + \lambda_3 = 1 + 2 + 3 = 6 \), we have that \( (1, 2, 3) \in S_2^3 \) and therefore \( (1, 2, 3) \in V^3 \). We can calculate the dependent radius \( \lambda_4 \), associated to the 1,2,3, which from Proposition 1.14 is positive and we have that

\[
\lambda_4 := \frac{1920 - 192(\lambda_1 + \lambda_2 + \lambda_3) + 24(\lambda_1 \lambda_2 + \lambda_1 \lambda_3 + \lambda_2 \lambda_3) - 4\lambda_1 \lambda_2 \lambda_3}{192 - 24(\lambda_1 + \lambda_2 + \lambda_3) + 4(\lambda_1 \lambda_2 + \lambda_1 \lambda_3 + \lambda_2 \lambda_3) - \lambda_1 \lambda_2 \lambda_3} = \frac{504}{43}.
\]

So, we have the A-point \((1, 2, 3, 504/43)\) which belongs to the set \( V_4^3 \).

Now, using Theorem 1.1 for \( \tau = 43/8 \), we have that the system

\[
\begin{align*}
\dot{x} &= y, \\
\dot{y} &= -x + \varepsilon \left( \frac{43}{8} y^2 - \frac{581}{20} y^5 + \frac{5887}{128} y^8 - \frac{1323}{64} y^2 \right) (1 - x^2),
\end{align*}
\]

with \( 0 < \varepsilon \ll 1 \) has exactly, the limit cycles \( x^2 + y^2 = 1 + O(\varepsilon), x^2 + y^2 = 2 + O(\varepsilon), x^2 + y^2 = 3 + O(\varepsilon) \) and \( x^2 + y^2 = (504/43) + O(\varepsilon) \).

Since \( 1 < 2 < 3 < 504/43 \), the limit cycles \( x^2 + y^2 = 1 + O(\varepsilon), x^2 + y^2 = 3 + O(\varepsilon) \) are unstable and the limit cycles \( x^2 + y^2 = 2 + O(\varepsilon), x^2 + y^2 = (504/43) + O(\varepsilon) \) are stable.

From Theorem 1.1 we have for the system (4.2) that, if we change \( \tau \) from 43/8 to \( -43/8 \) the unstable limit cycles \( x^2 + y^2 = 1 + O(\varepsilon), x^2 + y^2 = 3 + O(\varepsilon) \) become stable and the stable limit cycles \( x^2 + y^2 = 2 + O(\varepsilon), x^2 + y^2 = (504/43) + O(\varepsilon) \) become unstable.

Example 4.4. We consider \( \lambda_i = i \) for \( i = 1, 2, \ldots, 6 \). These \( \lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5, \lambda_6 \) satisfy our assertions, since \( \lambda_i \neq \lambda_j \) for all \( i \neq j \) where \( i, j = 1, 2, 3, 4, 5, 6 \) and are positive. It is easy to show, after some calculations, that \( (1, 2, 3, 4, 5, 6) \in V^6 \).

We can calculate the dependent radius \( \lambda_7 \), associated to the 1,2,3,4,5,6, which from Proposition 1.14 is positive and we have that \( \lambda_7 = 13337/690 \). So, we have the A-point \((1, 2, 3, 4, 5, 6, 13337/690)\) which belongs to the set \( V_6^5 \).

Therefore, from Theorem 1.1 exists a system of the form (1.1), where \( 0 < \varepsilon \ll 1 \) and \( f \) is an odd polynomial of degree 13, which has exactly the limit cycles:

\[
\begin{align*}
x^2 + y^2 &= 1 + O(\varepsilon), x^2 + y^2 = 2 + O(\varepsilon), x^2 + y^2 = 3 + O(\varepsilon), x^2 + y^2 = 4 + O(\varepsilon), x^2 + y^2 = 5 + O(\varepsilon), x^2 + y^2 = 6 + O(\varepsilon), x^2 + y^2 = (13337/690) + O(\varepsilon).
\end{align*}
\]

Example 4.5. We consider \( \lambda_1 = 7, \lambda_2 = 701/100 \). It is easy to show, after some calculations, that \( (7, 701/100) \in V^2 \). We can calculate the dependent radius \( \lambda_3 \), associated to the 7,701/100, which from Proposition 1.14 is positive and we have that \( \lambda_3 = 5204/1703 \). So, we have the A-point \((7, 701/100, 5204/1703)\) which belongs to the set \( V_3^2 \).
Now, using Theorem 1.1 for \( \tau = -2179840 \), we have that the system

\[
\dot{x} = y, \\
\dot{y} = -x + \varepsilon \left( -2179840y^5 + 12351224y^3 - 25536028y \right) (1 - x^2),
\]

with \( 0 < \varepsilon \ll 1 \) has exactly, the limit cycles \( x^2 + y^2 = 7 + O(\varepsilon) \), \( x^2 + y^2 = (701/100) + O(\varepsilon) \) and \( x^2 + y^2 = (5204/1703) + O(\varepsilon) \).

Since \( 5204/1703 < 7 < 701/100 \), the limit cycles \( x^2 + y^2 = (5204/1703) + O(\varepsilon) \), \( x^2 + y^2 = (701/100) + O(\varepsilon) \) are unstable and the limit cycle \( x^2 + y^2 = 7 + O(\varepsilon) \) is stable.

Since \( \sqrt{\lambda_1} \) and \( \sqrt{\lambda_2} \) have very small difference (\( |\sqrt{\lambda_1} - \sqrt{\lambda_2}| = \frac{10\sqrt{7} - \sqrt{701}}{10} \approx 0.0019 \)), the qualitative and quantitative image that one gets using a program, may give the mis impression that system (4.3) has a semistable limit cycle. This happens because the stable limit cycle \( x^2 + y^2 = 7 + O(\varepsilon) \) lies close enough to the unstable limit cycle \( x^2 + y^2 = (701/100) + O(\varepsilon) \). This of course is prospective since a priori we have chosen the \( \lambda_1 \) and \( \lambda_2 \) so as to be close enough the one to the other. So, the two limit cycles \( x^2 + y^2 = 7 + O(\varepsilon) \) and \( x^2 + y^2 = (701/100) + O(\varepsilon) \), create “one system with one pseudosemistable limit cycle” as we can say, since the two limit cycles together behave like a semistable limit cycle.

**Remark 4.6.** It is easy to see, according to Remark 1.17 that system (1.1) with \( n = 1 \) can’t have “a system with a pseudosemistable limit cycle” as we mean above “the system with a pseudosemistable limit cycle”.

**Example 4.7.** We consider \( \lambda_1 = 7 \). This \( \lambda_1 \) belongs to \( S^1_2 \). We know from Remark 1.17 that the point \((7, \lambda_2) \in S^1_2 \), where \( \lambda_2 \) is the dependent radius associated to the 7.

We calculate the dependent radius \( \lambda_2 \), associated to the 7, (which from Proposition 1.14 is positive) and we have that

\[
\lambda_2 := \frac{24 - 4\lambda_1}{4 - \lambda_1} = \frac{24 - 28}{4 - 7} = \frac{4}{3}.
\]

So, we have the A-point \((7, 4/3) \) which belongs to the set \( V^1_2 \).

Now, using Theorem 1.3 for \( \tau = 6 \), we have that the system

\[
\dot{x} = y, \\
\dot{y} = -x + \varepsilon \left( 6y^3 - 7y \right) (1 - x^2),
\]

with \( 0 < \varepsilon \ll 1 \) has exactly, the limit cycles \( x^2 + y^2 = 7 + O(\varepsilon) \) and \( x^2 + y^2 = (4/3) + O(\varepsilon) \).

Since \( 4/3 < 7 \), the limit cycle \( x^2 + y^2 = (4/3) + O(\varepsilon) \) is unstable and the limit cycle \( x^2 + y^2 = 7 + O(\varepsilon) \) is stable.

From Theorem 1.3 we have for the system (4.4) that, if we change \( \tau \) from 6 to \(-6 \) the unstable limit cycle \( x^2 + y^2 = (4/3) + O(\varepsilon) \) becomes stable and the stable limit cycle \( x^2 + y^2 = 7 + O(\varepsilon) \) becomes unstable.

**APPENDIX**

**Proof of Lemma 1.10** Clearly, for \( n \in \mathbb{N}, n \geq 3 \),

\[
2(n + 2) + \frac{1}{2(n + 1)} \sum_{i_1, i_2 = 1}^{n} \lambda_{i_1} \lambda_{i_2} - \frac{1}{4n(n + 1)} \sum_{i_1, i_2, i_3 = 1}^{n} \lambda_{i_1} \lambda_{i_2} \lambda_{i_3} + \ldots
\]
if and only if
\[
\frac{(-1)^k}{2^{k-1}(n-k+3)\ldots(n+1)} \sum_{i_1,\ldots,i_k=1 \atop i_1<\ldots<i_k}^{n} \lambda_{i_1}\ldots\lambda_{i_k} + \cdots + \frac{(-1)^n}{2^{n-2}(n+1)!} \prod_{i_1=1}^{n} \lambda_{i_1}.
\]
\[
= 2(n+1) + \frac{1}{2n} \sum_{i_1,i_2=1 \atop i_1<i_2}^{n} \lambda_{i_1}\lambda_{i_2} - \frac{1}{4(n-1)n} \sum_{i_1,i_2,i_3=1 \atop i_1<i_2<i_3}^{n} \lambda_{i_1}\lambda_{i_2}\lambda_{i_3} + \cdots
\]
\[
+ \frac{(-1)^k}{2^{k-1}(n-k+2)(n-k+3)\ldots(n+1)} \sum_{i_1,\ldots,i_k=1 \atop i_1<\ldots<i_k}^{n} \lambda_{i_1}\ldots\lambda_{i_k} + \cdots + \frac{(-1)^n}{2^{n-1}n!} \prod_{i_1=1}^{n} \lambda_{i_1}
\]
if and only if
\[
\frac{1}{4n(n+1)} \sum_{i_1,i_2=1 \atop i_1<i_2}^{n} \lambda_{i_1}\lambda_{i_2} - \frac{2}{8(n-1)n(n+1)} \sum_{i_1,i_2,i_3=1 \atop i_1<i_2<i_3}^{n} \lambda_{i_1}\lambda_{i_2}\lambda_{i_3} + \cdots
\]
\[
+ \frac{(-1)^k(k-1)}{2^{k-1}(n-k+2)(n-k+3)\ldots(n+1)} \sum_{i_1,\ldots,i_k=1 \atop i_1<\ldots<i_k}^{n} \lambda_{i_1}\ldots\lambda_{i_k} + \cdots + \frac{(-1)^n(n-1)}{2^n(n+1)!} \prod_{i_1=1}^{n} \lambda_{i_1} = 1,
\]
and the first equivalence has been proved. Similarly, one can prove and the rest

**Proof of Proposition 1.14.** To prove that the dependent radius \(\lambda_{n+1}, n \in \mathbb{N}, n \geq 2\),
associated to the radii \(\lambda_1, \lambda_2, \ldots, \lambda_n\) is positive when \((\lambda_1, \lambda_2, \ldots, \lambda_n) \in V^n, n \in \mathbb{N},
n \geq 2\), it suffices to show that both numerator and denominator of (1.6) are of
the same sign.

We will check the case where \((\lambda_1, \lambda_2, \ldots, \lambda_{n-1}, \lambda_n) \in S^n, n \in \mathbb{N}, n \geq 2\). Similarly,
one can prove and the other cases.

In the set \(S^n, n \in \mathbb{N}, n \geq 2\), we have \(\sum_{i=1}^{n} \lambda_i < \bar{s}^n\). Now, for \(n \in \mathbb{N}, n \geq 3\),
using the definition of \(s^n\) and multiplying the last inequality by \(-2^n(n+1)!\) we
have
\[
2^{n+1}(n+2)! - 2^n(n+1)! \sum_{i_1=1}^{n} \lambda_{i_1} + 2^{n-1}n! \sum_{i_1,i_2=1 \atop i_1<i_2}^{n} \lambda_{i_1}\lambda_{i_2} - \cdots + 4(-1)^n \prod_{i_1=1}^{n} \lambda_{i_1} > 0,
\]
which shows that the numerator of (1.6) is positive.

Since \(\sum_{i=1}^{n} \lambda_i < \bar{s}^n\) in the set \(S^n\), we have that \(-\sum_{i=1}^{n} \lambda_i > -\bar{s}^n\). Using this
observation we obtain the first inequality for the denominator of (1.6).
\[
2^n(n+1)! - 2^{n-1}n! \sum_{i_1=1}^{n} \lambda_{i_1} + 2^{n-2}(n-1)! \sum_{i_1,i_2=1 \atop i_1<i_2}^{n} \lambda_{i_1}\lambda_{i_2} - \cdots + (-1)^n \prod_{i_1=1}^{n} \lambda_{i_1}
\]
\[
> 2^n(n+1)! - 2^{n-1}n!\bar{s}^n + 2^{n-2}(n-1)! \sum_{i_1,i_2=1 \atop i_1<i_2}^{n} \lambda_{i_1}\lambda_{i_2} - \cdots + (-1)^n \prod_{i_1=1}^{n} \lambda_{i_1}
\]
\[= 2^n(n+1)! - 2^n n!(n+2) - 2^{n-2} \frac{n!}{n+1} \sum_{i_1, i_2=1}^{n} \lambda_{i_1} \lambda_{i_2} + \cdots - \frac{2(-1)^n}{n+1} \prod_{i_1=1}^{n} \lambda_{i_1} \]

\[+ 2^{n-2}(n-1)! \sum_{i_1, i_2=1}^{n} \lambda_{i_1} \lambda_{i_2} - \cdots + (-1)^n \prod_{i_1=1}^{n} \lambda_{i_1} \]

\[= -2^n n! + 2^n n! \tilde{s}^n > -2^n n! + 2^n n! = 0.\]

Here, we have used in the first equality the definition of \(\tilde{s}^n\) for \(n \in \mathbb{N}, n \geq 3\) and in the last inequality that \(\tilde{s}^n > 1\) in the set \(S_1^1\).

So, we proved that both numerator and denominator of (1.6) when \(n \in \mathbb{N}, n \geq 3\), are positive, which show that the dependent radius \(\lambda_{n+1}\) is positive if \((\lambda_1, \ldots, \lambda_n) \in S_1^n, n \in \mathbb{N}, n \geq 3\).

In the case where \(n = 2\), it is easy to show that the dependent radius \(\lambda_3\) associated to the radii \(\lambda_1, \lambda_2\) is positive if \((\lambda_1, \lambda_2) \in S_1^2\), since in that case both numerator and denominator of (1.6) with \(n = 2\), are positive.

If \(n = 1\), it is easy to show that the dependent radius \(\lambda_2\) associated to the radius \(\lambda_1\) is positive if \(\lambda_1 \in V^1\), since in that case both numerator and denominator of (1.7) are of the same sign.

Let us now show the inverse. Let \(\lambda_1, \ldots, \lambda_n, n \in \mathbb{N}, n \geq 2\), be distinct positive real numbers so that the dependent radius \(\lambda_{n+1}\), associated to the radii \(\lambda_1, \lambda_2, \ldots, \lambda_n\) is positive.

First, we examine the case where both numerator and denominator of \(\lambda_{n+1}\) are positive.

Since we suppose that the numerator of \(\lambda_{n+1}\) is positive, we have that

\[2^{n+1}(n+2)! - 2^n(n+1)! \sum_{i_1=1}^{n} \lambda_{i_1} + 2^{n-1} n! \sum_{i_1, i_2=1}^{n} \lambda_{i_1} \lambda_{i_2} - \cdots + 4(-1)^n \prod_{i_1=1}^{n} \lambda_{i_1} > 0,\]

and dividing this inequality by \(-2^n(n+1)\) we have that \(\sum_{i_1=1}^{n} \lambda_{i_1} < \tilde{s}^n\).

Since we suppose that the denominator of \(\lambda_{n+1}\) is positive, we have that

\[2^n(n+1)! - 2^{n-1} n! \sum_{i_1=1}^{n} \lambda_{i_1} + 2^{n-2}(n-1)! \sum_{i_1, i_2=1}^{n} \lambda_{i_1} \lambda_{i_2} - \cdots + (-1)^n \prod_{i_1=1}^{n} \lambda_{i_1} > 0,\]

and dividing this inequality by \(-2^{n-1} n!\) we have that \(\sum_{i_1=1}^{n} \lambda_{i_1} < \tilde{s}^n\).

Now, we have the following possibilities: \(\tilde{s}^n = \tilde{s}^n\) or \(\tilde{s}^n > \tilde{s}^n\) or \(\tilde{s}^n < \tilde{s}^n\), where \(n \in \mathbb{N}, n \geq 2\).

In the case where \(\tilde{s}^n = \tilde{s}^n\) we know from Lemma (1.10) that \(\tilde{s}^n = 1\) and hence \((\lambda_1, \lambda_2, \ldots, \lambda_n) \in S_1^n, n \in \mathbb{N}, n \geq 2\).

In the case where \(\tilde{s}^n > \tilde{s}^n\) we know from Lemma (1.10) that \(\tilde{s}^n < 1\) and hence \((\lambda_1, \lambda_2, \ldots, \lambda_n) \in S_2^n, n \in \mathbb{N}, n \geq 2\).

In the case where \(\tilde{s}^n < \tilde{s}^n\) we know from Lemma (1.10) that \(\tilde{s}^n > 1\) and hence \((\lambda_1, \lambda_2, \ldots, \lambda_n) \in S_1^n, n \in \mathbb{N}, n \geq 2\).

Let us now examine the case where both numerator and denominator of \(\lambda_{n+1}\) are negative.
Since we suppose that the numerator of $\lambda_{n+1}$ is negative, we have that
\[ 2^{n+1}(n+2)! - 2^n(n+1)! \sum_{i_1=1}^{n} \lambda_{i_1} + 2^{n-1}n! \sum_{i_1,i_2=1}^{n} \lambda_{i_1} \lambda_{i_2} - \cdots + 4(-1)^n \prod_{i_1=1}^{n} \lambda_{i_1} < 0, \]
and dividing this inequality by $-2^n(n+1)!$ we have that $\sum_{i_1=1}^{n} \lambda_{i_1} > \bar{s}^n$.

Since we suppose that the denominator of $\lambda_{n+1}$ is negative, we have that
\[ 2^n(n+1)! - 2^{n-1}n! \sum_{i_1=1}^{n} \lambda_{i_1} + 2^{n-2}(n-1)! \sum_{i_1,i_2=1}^{n} \lambda_{i_1} \lambda_{i_2} - \cdots + (-1)^n \prod_{i_1=1}^{n} \lambda_{i_1} < 0, \]
and dividing this inequality by $-2^{n-1}n!$ we have that $\sum_{i_1=1}^{n} \lambda_{i_1} > \bar{s}^n$.

Now, we have the following possibilities: $\bar{s}^n = \hat{s}^n$ or $\bar{s}^n > \hat{s}^n$ or $\bar{s}^n < \hat{s}^n$, where $n \in \mathbb{N}$, $n \geq 2$.

In the case where $\bar{s}^n = \hat{s}^n$ we know from Lemma 1.10 that $\bar{s}^n = 1$ and hence $(\lambda_1, \lambda_2, \ldots, \lambda_n) \in S^0_n$, $n \in \mathbb{N}$, $n \geq 2$.

In the case where $\bar{s}^n > \hat{s}^n$ we know from Lemma 1.10 that $\bar{s}^n < 1$ and hence $(\lambda_1, \lambda_2, \ldots, \lambda_n) \in S^0_n$, $n \in \mathbb{N}$, $n \geq 2$.

In the case where $\bar{s}^n < \hat{s}^n$ we know from Lemma 1.10 that $\bar{s}^n > 1$ and hence $(\lambda_1, \lambda_2, \ldots, \lambda_n) \in S^0_n$, $n \in \mathbb{N}$, $n \geq 2$.

We have thus proved the inverse of Proposition 1.14 for $n \in \mathbb{N}$, $n \geq 2$. In fact we proved a stronger result. Let $\lambda_1, \lambda_2, \ldots, \lambda_n$, $n \in \mathbb{N}$, $n \geq 2$, be distinct positive real numbers. Supposing that both numerator and denominator of the positive dependent radius $\lambda_{n+1}$, $n \in \mathbb{N}$, $n \geq 2$, associated to the radii $\lambda_1, \lambda_2, \ldots, \lambda_n$ are positive, then $(\lambda_1, \lambda_2, \ldots, \lambda_n) \in \bigcup_{i=1}^{n} S^0_i$, $n \in \mathbb{N}$, $n \geq 2$. If we suppose that both numerator and denominator of the positive dependent radius $\lambda_{n+1}$, $n \in \mathbb{N}$, $n \geq 2$, associated to the radii $\lambda_1, \lambda_2, \ldots, \lambda_n$ are negative, then $(\lambda_1, \lambda_2, \ldots, \lambda_n) \in \bigcup_{i=1}^{n} S^1_i$, $n \in \mathbb{N}$, $n \geq 2$.

If $n = 1$, let $\lambda_1$ be a positive real number so that the dependent radius $\lambda_2$ associated to the radius $\lambda_1$ is positive.

First, we examine the case where both numerator and denominator of $\lambda_2$ are positive. In that case we have for the numerator that $24 - 4\lambda_1 > 0$ which implies that $\lambda_1 < 6$ and for the denominator that $4 - \lambda_1 > 0$ which implies that $\lambda_1 < 4$. Combining the last two results about $\lambda_1$, we have that $0 < \lambda_1 < 4$ and hence $\lambda_1 \in S^1_1$.

Let now examine the case where both numerator and denominator of $\lambda_2$ are negative. In that case we have for the numerator that $24 - 4\lambda_1 < 0$ which implies that $\lambda_1 > 6$ and for the denominator that $4 - \lambda_1 < 0$ which implies that $\lambda_1 > 4$. Combining the last two results about $\lambda_1$, we have that $6 < \lambda_1 < +\infty$ and hence $\lambda_1 \in S^1_2$.

So, we proved that, if $\lambda_1$ is a positive real number so that the dependent radius $\lambda_2$ associated to the radius $\lambda_1$ is positive, then $\lambda_1 \in V^1$. The proof of the proposition is complete.

Acknowledgements. The author wishes to thank Nikolaos Alikakos for considering the generalized Van der Pol equation (1.2) in the particular case where $f$ is an odd polynomial of degree 5. I am grateful to Charalambos Evripidou for several helpful and stimulating discussions and comments. The author would also like to thank Yiorgos-Sokratis Smyrlis for his assistance in technical matters in
the preparation of this paper and Dimitris Ioakim for improving the use of the English language. I would also like to express my sincere gratitude to the anonymous referees for their useful comments and valuable suggestions, which led to the improvement of this article.
