 ORBITAL STABILITY OF SOLITARY WAVES FOR A 2D-BOUSSINESQ SYSTEM

ALEX M. MONTES, JOSÉ R. QUINTERO

Abstract. In this article, using a variational approach, we establish the nonlinear orbital stability of ground state solitary waves for a 2D Boussinesq-Benney-Luke system that models the evolution of three dimensional long water waves with small amplitude in the presence of surface tension.

1. Introduction

The focus of the present work is the two-dimensional Boussinesq-Benney-Luke type system

\begin{align}
(I - \frac{\mu}{2} \Delta) \eta_t + \Delta \Phi - \frac{2\mu}{3} \Delta^2 \Phi + \epsilon \nabla \cdot (\eta \nabla \Phi) &= 0, \\
(I - \frac{\mu}{2} \Delta) \Phi_t + \eta - \mu \sigma \Delta \eta + \frac{\epsilon}{2} |\nabla \Phi|^2 &= 0,
\end{align}

(1.1)

that arises in the study of the evolution of small amplitude long water waves in the presence of surface tension (see Quintero and Montes [11]). Here μ, ε are small positive parameters, σ^{-1} is the Bond number (associated with the surface tension) and the functions η(t, x, y) and Φ(t, x, y) denote the wave elevation and the potential velocity on the bottom z = 0, respectively. The aspect that we study about the system (1.1) is the orbital stability of solitary wave solutions. It is well know that the study of this kind of states of motion is very important to understand the behavior of many physical systems.

A special feature on the Boussinesq system (1.1) is that the Benney-Luke equation (see [13]) and the Kadomtsev-Petviashvili (KP) equation can be derived up to some order with respect to μ and ε from system (1.1). Moreover, for small wave speed and large surface tension, is showed in [11] (see also [6]) that a suitable renormalized family of solitary waves of the Boussinesq system (1.1) converges to a nontrivial solitary wave for the (KP-I) equation. We will use this fact in the stability analysis.

One of the main characteristics behind water wave systems is the existence of a Hamiltonian structure which characterizes travelling waves as critical points of the action functional and also provides relevant information for the stability of travelling...
waves. In our particular Boussinesq system (1.1), the Hamiltonian structure is given by
\[
\left( \eta_t \Phi_t \right) = \mathcal{B} \mathcal{H}' \left( \eta \Phi \right), \quad \mathcal{B} = \left( I - \frac{\mu}{2} \Delta \right)^{-1} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},
\]
where the Hamiltonian \( \mathcal{H} \) is defined as
\[
\mathcal{H} \left( \eta \Phi \right) = \frac{1}{2} \int_{\mathbb{R}^2} \left( |\nabla \Phi|^2 + \eta^2 + 2\mu \Delta \Phi^2 + \mu \sigma |\nabla \eta|^2 + \epsilon \eta |\nabla \Phi|^2 \right) \, dx \, dy.
\]
On the other hand, by Noether’s Theorem, there is a functional \( Q \) (named the Charge) which is conserved in time for classical solutions defined formally as
\[
Q \left( \eta \Phi \right) = \frac{1}{2} \langle \mathcal{B}^{-1} \partial_x \left( \eta \Phi \right), \left( \eta \Phi \right) \rangle = -\frac{1}{2} \int_{\mathbb{R}^2} \left( 2\eta \Phi_x + \mu \eta_x \Delta \Phi \right) \, dx \, dy.
\]
We will see that travelling waves of wave speed \( c \) for the Boussinesq system (1.1) corresponds to stationary solutions of the modulated system
\[
\left( \eta_t \Phi_t \right) = \mathcal{B} \mathcal{H}_c' \left( \eta \Phi \right),
\]
where \( \mathcal{H}_c(Y) = \mathcal{H}(Y) + c \mathcal{Q}(Y) \). In other words, solutions of the system
\[
\mathcal{H}'(Y) + c \mathcal{Q}'(Y) = 0.
\]
We note from the Hamiltonian structure that the well definition of the functionals \( \mathcal{H} \) and \( \mathcal{H}_c \) require having \( \eta, \nabla \Phi \in H^1(\mathbb{R}^2) \). These conditions already characterize the natural space (energy space) to look for travelling waves solutions of the system Boussinesq-Benney-Luke, as shown in the preliminary section. It is important to mention that using the conservation in time of the Hamiltonian, A. Montes et. al. (see [7]) established the existence of global solutions for the Cauchy problem associated with the system (1.1) and the initial condition in the energy space. On the other hand, J. Quintero and A. Montes in [11] showed the existence of solitary waves (travelling wave solutions in the energy space) by using a variational approach in which weak solutions correspond to critical points of an energy under a special constrain.

Regarding the stability issue, we need to recall that M. Grillakis, J. Shatah and W. Strauss in [4] gave a general result used to establish orbital stability of solitary waves for a class of abstract Hamiltonian systems. In this case, solitary waves of least energy \( Y_c \) are minimums of the action functional \( \mathcal{H}_c \) and the stability analysis depends on the positiveness of the symmetric operator \( \mathcal{H}_c''(Y_c) \) in a neighborhood of the solitary wave \( Y_c \), except possibly in two directions, and also the strict convexity of the real function
\[
d_1(c) = \inf \{ \mathcal{H}_c(Y) : Y \in \mathcal{M}_c \},
\]
where \( \mathcal{M}_c \) is a suitable set. The verification of the positiveness of \( \mathcal{H}_c''(Y_c) \) is much simpler for one-dimensional spatial problems since the spectral analysis for the operator \( \mathcal{H}_c''(Y_c) \) is reduced to studying the eigenvalues of an ordinary differential equation which at \( \pm \) infinity becomes to an ordinary differential equation with constant coefficients (see [1] [8] [12]). The key fact to obtain stability in those cases is that in the one dimensional case solitary waves are unique up to translations, and \( d_1 \) can be rescaled allowing to establish the strict convexity \( d_1(c) \) in a direct way (see [1] [8] [12]). In the two-dimensional spatial case, we have a harder task to overcome using Grillakis et al. approach since the spectral analysis is not straightforward for our problem. In order to avoid making the spectral analysis required...
in Grillakis et al. work, we used a direct approach to prove orbital stability of ground state solitary wave solutions of the system (1.1) in the case of wave speed $c$ near $1^{-}$, using strongly the variational characterization of $d_{1}$, as done for other 2D models: see Shatah for nonlinear Klein Gordon equations [14], Quintero for the 2D Benney-Luke equation [9] and also in the case of a 2D Boussinesq-KdV type system [10], Saut for the KP equation [2], Fukuizumi for the nonlinear Schrödinger equation with harmonic potential [3] and Liu for the generalized KP equation [5], among others.

This article is organized as follows. In section 2, we present preliminaries related with the existence of solitons (solitary wave solutions) for the system Boussinesq-Benney-Luke and the link between solitons for the system (1.1) and the (KP) equation. In section 3, we prove the strict convexity of $d_{1}$ for $c \in (0, 1)$, but near 1. In section 4, we establish the orbital stability result.

2. Preliminaries

To simplify the computation, we rescale the parameters $\mu$ and $\epsilon$ from the system (1.1) by defining

$$
\tilde{\eta}(t, x, y) = \frac{1}{\epsilon} \eta\left(\frac{t}{\sqrt{\mu}}, \frac{x}{\sqrt{\mu}}, \frac{y}{\sqrt{\mu}}\right), \quad \tilde{\Phi}(t, x, y) = \frac{\sqrt{\mu}}{\epsilon} \Phi\left(\frac{t}{\sqrt{\mu}}, \frac{x}{\sqrt{\mu}}, \frac{y}{\sqrt{\mu}}\right).
$$

So, by a solitary wave solution for the system (1.1) we mean a solution for the rescaled system of the form

$$
\eta(t, x, y) = u(x - ct, y), \quad \Phi(t, x, y) = v(x - ct, y),
$$

where $c$ denotes the speed of the wave. Then, one sees that the solitary wave profile $(u, v)$ should satisfy the system

$$
\begin{align*}
\frac{2}{3} \Delta^{2} v - \Delta v + c \left(I - \frac{1}{2} \Delta\right) u_x - \nabla \cdot (u \nabla v) &= 0, \\
\mu - \sigma \Delta u - c \left(I - \frac{1}{2} \Delta\right) v_x + \frac{1}{2} |\nabla v|^{2} &= 0.
\end{align*}
\tag{2.1}
$$

Our stability analysis of the solitary wave solutions will be perform in the following appropriate spaces. Recall that the standard Sobolev space $H^{k}(\mathbb{R}^{2})$, $k \in \mathbb{Z}^{+}$, is the Hilbert space defined as the closure of $C_{0}^{\infty}(\mathbb{R}^{2})$ with inner product

$$
\langle u, v \rangle_{H^{k}} = \sum_{|\alpha| \leq k} \int_{\mathbb{R}^{2}} D^{\alpha} u \cdot D^{\alpha} v \, dx.
$$

We denote $\mathcal{V}$ the closure of $C_{0}^{\infty}(\mathbb{R}^{2})$ with respect to the norm given by

$$
\|v\|_{\mathcal{V}} := \int_{\mathbb{R}^{2}} \left(\nabla v|^{2} + |\Delta v|^{2}\right) \, dx \, dy = \int_{\mathbb{R}^{2}} \left(v_{x}^{2} + v_{y}^{2} + v_{xx}^{2} + v_{xy}^{2} + v_{yy}^{2}\right) \, dx \, dy.
$$

Note that $\mathcal{V}$ is a Hilbert space with respect to the inner product

$$
\langle v, w \rangle_{\mathcal{V}} = \langle v_{x}, w_{x} \rangle_{H^{1}(\mathbb{R}^{2})} + \langle v_{y}, w_{y} \rangle_{H^{1}(\mathbb{R}^{2})}.
$$

Also, we define the energy space $\mathcal{X} = H^{1}(\mathbb{R}^{2}) \times \mathcal{V}$, which is a Hilbert space with respect to the norm

$$
\|\langle u, v \rangle\|_{\mathcal{X}} = \|u\|_{H^{1}(\mathbb{R}^{2})}^{2} + \|v\|_{\mathcal{V}}^{2} = \int_{\mathbb{R}^{2}} \left(u^{2} + |\nabla u|^{2} + |\nabla v|^{2} + |\Delta v|^{2}\right) \, dx \, dy.
$$
In fact, note that the existence of solitary wave solutions for the Boussinesq-Benney-Luke system \((1.1)\) for \(\sigma > 0\) and \(0 < c < \min\{1, \frac{8\sigma}{\pi^2}\}\), by using the Concentration-Compactness principle and the existence of a local compact embedding result. The strategy was to consider the following minimization problem

\[ J_c(u, v) = I_c(u, v) + G(u, v), \]

where the functionals \(I_c\) and \(G\) are defined on the space \(X\) by

\[ I_c(u, v) = I_1(u, v) + I_{2,c}(u, v), \]

\[ I_1(u, v) = \int_{\mathbb{R}^2} (u^2 + \sigma|\nabla u|^2 + |\nabla v|^2 + \frac{2}{3}(\Delta v)^2) \, dx \, dy, \]

\[ I_{2,c}(u, v) = -c \int_{\mathbb{R}^2} (2uv_x + u_x \Delta v) \, dx \, dy, \]

\[ G(u, v) = \int_{\mathbb{R}^2} u|\nabla v|^2 \, dx \, dy. \]

In fact, note that \(I_c, G \in C^1(X, \mathbb{R})\) and its derivatives in \((u, v)\) in the direction of \((U, V)\) are given by

\[ \langle I'_c(u, v), (U, V) \rangle = 2 \int_{\mathbb{R}^2} (uU + \sigma \nabla u \cdot \nabla U + \nabla v \cdot \nabla V + \frac{2}{3} \Delta v \Delta V) \, dx \, dy \]

\[ - c \int_{\mathbb{R}^2} (2uv_x + 2v_x U + u_x \Delta V + \Delta u U_x) \, dx \, dy, \]

\[ \langle G'(u, v), (U, V) \rangle = \int_{\mathbb{R}^2} (|\nabla v|^2 U + 2u \nabla v \cdot \nabla V) \, dx \, dy. \]

Then we see that

\[ J'_c(u, v) = 2 \left( \frac{u - \sigma \Delta u - c(I - \frac{1}{2} \Delta) v_x + \frac{1}{2} |\nabla v|^2}{\frac{2}{3} \Delta^2 v - \Delta v + c(I - \frac{1}{2} \Delta) u_x - \nabla \cdot (u \nabla v)} \right), \]

meaning that critical points of the functional \(J_c\) satisfy the solitary wave system \((2.1)\).

2.1. **Existence of solitary waves.** Quintero and Montes [11] established the existence of solitary wave solutions for the Boussinesq-Benney-Luke system \((1.1)\) for \(\sigma > 0\) and \(0 < c < \min\{1, \frac{8\sigma}{\pi^2}\}\), by using the Concentration-Compactness principle and the existence of a local compact embedding result. The strategy was to consider the following minimization problem

\[ \mathcal{I}_c := \inf \{I_c(u, v) : (u, v) \in X \text{ with } G(u, v) = 1\}. \quad (2.2) \]

The existence of solitary waves is consequence of the following results [11], which we will use throughout this work. Next, we assume that \(\sigma > 0\) and \(0 < c < \min\{1, \frac{8\sigma}{\pi^2}\}\).

**Lemma 2.1.** The functional \(I_c\) is nonnegative and there are positive constants \(C_1(\sigma, c) < C_2(\sigma, c)\) defined as

\[ C_1(\sigma, c) = \min\{1 - c, \sigma(1 - c), \frac{2}{3} - \frac{c}{4\sigma}\}, \quad C_2(\sigma, c) = \max\{1 + c, \frac{2}{3} + \frac{c}{2}, \sigma + \frac{c}{2}\} \]

such that

\[ C_1(\sigma, c)I_c(u, v) \leq ||(u, v)||^2_X \leq C_2(\sigma, c)I_c(u, v). \quad (2.3) \]

Furthermore, \(\mathcal{I}_c\) is finite and positive.

**Theorem 2.2.** If \((u_0, v_0)\) is a minimizer for problem \((2.2)\), then \((u, v) = -k(u_0, v_0)\) is a nontrivial solution of \((2.1)\) for \(k = \frac{3}{2}\mathcal{I}_c\).
**Theorem 2.3.** If \( \{(u_m, v_m)\} \) is a minimizing sequence for (2.2), then there is a subsequence (which we denote the same), a sequence of points \((x_m, y_m) \in \mathbb{R}^2\), and a minimizer \((u_0, v_0) \in \mathcal{X}\) of (2.2), such that the translated functions

\[
(u_m, v_m) = (u_m(\cdot + x_m, \cdot + y_m), v_m(\cdot + x_m, \cdot + y_m))
\]

converge to \((u_0, v_0)\) strongly in \(\mathcal{X}\).

### 2.2. Link between solitary waves for (1.1) and the KP equation.

Assuming \(\sigma > 3/8\), \(c\) is close to \(-1\), and balancing the effects of nonlinearity and dispersion, Quintero and Montes \([11]\) established that a renormalized family of solitons of the Boussinesq-Benney-Luke system converges to a nontrivial soliton for a KP-I type equation. More precisely, set \(\sigma > 0, \epsilon > 0, \mu = \epsilon, c^2 = 1 - \epsilon\) and for a given couple \((u, v) \in \mathcal{X}\) define the functions \(z\) and \(w\) by

\[
u(x, y) = \epsilon^{1/2}z(X, Y), \quad v(x, y) = w(X, Y), \quad X = \epsilon^{1/2}x, \quad Y = \epsilon y.
\]

Then a simple calculation shows that

\[
I_1(u, v) = \epsilon^{1/2}I^{1, \epsilon}(z, w), \quad I_2(u, v) = \epsilon^{1/2}I^{2, \epsilon}(z, w),
\]

\[
I_{\epsilon}(u, v) = \epsilon^{1/2}I^\epsilon(z, w), \quad G(u, v) = G^\epsilon(z, w),
\]

where \(I^1, I^{2, \epsilon}, I^\epsilon\) and \(G^\epsilon\) are given by

\[
I^\epsilon(z, w) = I^{1, \epsilon}(z, w) + I^{2, \epsilon}(z, w),
\]

\[
I^{1, \epsilon}(z, w) = \int_{\mathbb{R}^2} \left( \epsilon^{-1} z^2 + \sigma (z_x^2 + \epsilon z_y^2) + \epsilon^{-1} w_x^2 + w_y^2 \right) dx dy + \frac{2}{3} \int_{\mathbb{R}^2} (w_{xx}^2 + 2 \epsilon w_{xy}^2 + \epsilon^2 w_{yy}^2) dx dy,
\]

\[
I^{2, \epsilon}(z, w) = -c \int_{\mathbb{R}^2} \left( 2 \epsilon^{-1} zw_x + z_x (w_{xx} + \epsilon w_{yy}) \right) dx dy,
\]

\[
G^\epsilon(z, w) = \int_{\mathbb{R}^2} \left( w_x^2 + \epsilon w_y^2 \right) dx dy.
\]

Note that if \(\sigma > 3/8\) then there is a family \(\{(u_c, v_c)\}_c\) such that

\[
I_{\epsilon}(u_c, v_c) = I_c, \quad G(u_c, v_c) = 1, \quad 0 < c < 1.
\]

Then, if we denote

\[
\mathcal{I}^\epsilon := \inf \{ I^\epsilon(z, w) : (z, w) \in \mathcal{X} \text{ with } G^\epsilon(z, w) = 1 \},
\]

there is a correspondent family \(\{(z^\epsilon, w^\epsilon)\}_c\) such that

\[
\mathcal{I}^\epsilon = I^\epsilon(z^\epsilon, w^\epsilon), \quad G^\epsilon(z^\epsilon, w^\epsilon) = 1, \quad I_c = \epsilon^{1/2}\mathcal{I}^\epsilon.
\]

We have the following results (see \([11]\)).

**Lemma 2.4.** Let \(\sigma > 3/8\). Then we have

\[
\lim_{\epsilon \to 0^+} \mathcal{I}^\epsilon = \lim_{\epsilon \to 0^+} I^\epsilon(z^\epsilon, w^\epsilon) = J^0 > 0,
\]

where

\[
J^0 = \inf \{ J^0(w) : w \in \mathcal{V}, G^0(w) = 1 \},
\]

\[
J^0(w) = \int_{\mathbb{R}^2} (w_x^2 + w_y^2 + (\sigma - \frac{1}{3}) w_{xx}^2) dx dy,
\]
\[ G^0(w) = \int_{\mathbb{R}^2} w^3 \, dx \, dy. \]

**Lemma 2.5.** Let \( \sigma > 3/8 \). Then we have

\[
\lim_{\epsilon \to 0^+} (z^\epsilon - \partial_x w^\epsilon) = 0 \quad \text{in} \quad L^2(\mathbb{R}^2).
\]

Moreover, there is a nontrivial distribution \( w_0 \in \mathcal{V} \) such that

\[
\lim_{\epsilon \to 0^+} \partial_x w^\epsilon = \partial_x w_0 \quad \text{in} \quad L^2(\mathbb{R}^2).
\]

Furthermore,

\[
\|z^\epsilon\|_{L^2(\mathbb{R}^2)} + \|\partial_x z^\epsilon\|_{L^2(\mathbb{R}^2)} = O(1), \quad \|\partial_{yy} w^\epsilon\|_{L^2(\mathbb{R}^2)} = O(\epsilon^{-1}),
\]

\[
\|\partial_x w^\epsilon\|_{L^2(\mathbb{R}^2)} + \|\partial_{xx} w^\epsilon\|_{L^2(\mathbb{R}^2)} = O(1).
\]

Using the previous lemmas, Quintero *et al.* showed that there are nontrivial distributions \( w_0 \in \mathcal{V}, z_0 \in H^1(\mathbb{R}^2) \) such that as \( \epsilon \to 0^+ \),

\[
w^\epsilon \to w_0 \quad \text{in} \quad \mathcal{V}, \quad z^\epsilon \to z_0 \quad \text{in} \quad H^1(\mathbb{R}^2),
\]

and \( \partial_x w_0 \) being a solution of the solitary wave equation for the (KP-I) type equation

\[
\left( u_x - (\sigma - \frac{1}{3}) u_{xxx} + 3uu_x \right)_x + uu_{yy} = 0.
\]

We shall use Lemmas 2.4 and 2.5 in our proof of stability.

### 3. Variational Approach for Stability

Recall that the solitary waves for the Boussinesq-Benney-Luke system \((1.1)\) are characterized as critical points of the functional defined on \( \mathcal{X} \) by

\[ J_c(u, v) = I_c(u, v) + G(u, v). \]

In particular, if

\[ K_c(u, v) = \langle J'_c(u, v), (u, v) \rangle \]

we have

\[ K_c(u, v) = 2I_c(u, v) + 3G(u, v) = 2J_c(u, v) + G(u, v). \]

Thus, on any critical point \((u, v)\) of the functional \( J_c \) we have that

\[
J_c(u, v) = \frac{1}{3} I_c(u, v), \tag{3.1}
\]

\[
J_c(u, v) = -\frac{1}{2} G(u, v), \tag{3.2}
\]

\[
I_c(u, v) = -\frac{3}{2} G(u, v). \tag{3.3}
\]

Now, define the set

\[ \mathcal{M}_c = \{ (u, v) \in \mathcal{X} : K_c(u, v) = 0, \ (u, v) \neq 0 \}. \]

Note that \( \mathcal{M}_c \) is just the “artificial constrain” for minimizing the functional \( J_c \) on \( \mathcal{X} \). We will see that the analysis of the orbital stability of ground states solutions depends upon some properties of the function \( d \) defined by

\[ d(c) = \inf \{ J_c(u, v) : (u, v) \in \mathcal{M}_c \}. \]
Then a direct computation shows that
\[ J_c = \{(u, v) \in \mathcal{M}_c : d(c) = J_c(u, v)\} \]
can be characterized as
\[ \mathcal{G}_c = \{(u, v) \in \mathcal{X} \setminus \{0\} : d(c) = \frac{1}{3} I_c(u, v) = -\frac{1}{2} G(u, v)\} \subset \mathcal{M}_c. \]

We note that there is a simple relationship between \( d_1 \) and \( d \), and so regarding the convexity of them. In fact,
\[ d(c) = \inf\{J_c(u, v) : (u, v) \in \mathcal{M}_c\} = 2 \inf\{H_c(u, v) : (u, v) \in \mathcal{M}_c\} = 2d_1(c). \]

In the next lemmas we present important variational properties of \( d(c) \).

**Lemma 3.1.** Let \( 0 < c < 1 \) and \( \sigma > 3/8 \). Then
1. \( d(c) \) exist and is positive.
2. \( d(c) = \inf\{\frac{1}{3} I_c(u, v) : K_c(u, v) \leq 0, (u, v) \neq 0\} \).

**Proof.** (1) Let \( (u, v) \in \mathcal{M}_c \), then we have that
\[ J_c(u, v) = \frac{1}{3} I_c(u, v) \geq 0. \]

This implies that \( d(c) \) exists. Now, Using the Young inequality and that the embedding \( H^1(\mathbb{R}^2) \hookrightarrow L^q(\mathbb{R}^2) \) is continuous for \( q \geq 2 \), we see that there is a constant \( C > 0 \) such that
\[ |G(u, v)| \leq C \left( \|u\|_{H^1(\mathbb{R}^2)}^3 + \|
abla v\|_{H^1(\mathbb{R}^2)}^3 \right) \quad (3.4) \]

Thus, using (2.3) we see that
\[ J_c(u, v) = \frac{1}{3} I_c(u, v) = -\frac{1}{2} G(u, v) \leq C \|u\|_{H^1(\mathbb{R}^2)}^3 \leq C (I_c(u, v))^3/2. \]

Then follows that \( \frac{1}{2} I_c(u, v) \geq C \), and this implies that \( d(c) \geq C > 0 \).

(2) For \( (u, v) \in \mathcal{X} \) such that \( K_c(u, v) \leq 0 \) we have that \( G(u, v) < 0 \). Define \( \alpha \in [0, 1] \) by
\[ \alpha = -\frac{2I_c(u, v)}{3G(u, v)}. \]

Then a direct computation shows that \( K_c(\alpha(u, v)) = 0 \). In other words, \( \alpha(u, v) \in \mathcal{M}_c \). So that,
\[ d(c) \leq J_c(\alpha(u, v)) = \frac{\alpha^2}{3} I_c(u, v) \leq \frac{1}{3} I_c(u, v). \]

Hence, we obtain
\[ d(c) \leq \inf\{\frac{1}{3} I_c(u, v) : K_c(u, v) \leq 0\}. \]

If \( (u, v) \in \mathcal{M}_c \), we see that \( J_c(u, v) = \frac{1}{3} I_c(u, v) \) and
\[ \inf\{\frac{1}{3} I_c(u, v) : K_c(u, v) \leq 0, (u, v) \neq 0\} \leq \inf\{J_c(u, v) : (u, v) \in \mathcal{M}_c\} = d(c). \]

Then the statement 2 of the lemma follows. \( \square \)
Lemma 3.2. Let $0 < c < 1$ and $\sigma > 3/8$. Then

1. If $\{ (u_m, v_m) \}$ is a minimizing sequence of $d(c)$, then there is a subsequence, which we denote the same, a sequence of points $(x_m, y_m) \in \mathbb{R}^2$, and $(w^c, v^c) \in X \setminus \{0\}$ such that the translated functions

$$(u_m(\cdot + x_m, \cdot + y_m), v_m(\cdot + x_m, \cdot + y_m))$$

converge to $(w^c, v^c)$ strongly in $X$, $(u^c, v^c) \in M_c$, $d(c) = J_c(u^c, v^c)$ and $(u^c, v^c)$ is a solution of (2.1). Moreover,

$$d(c) = \frac{4}{27} I_c^3,$$

(3.5)

where $I_c = \inf \{ I_c(u, v) : G(u, v) = 1, (u, v) \in X \}$.

2. Let $\{ (u_m, v_m) \}$ be a sequence in $X$ such that

$$\frac{1}{3} I_c(u_m, v_m) \to d(c) \quad \text{and} \quad J_c(u_m, v_m) \to \tilde{d} \leq d(c).$$

Then there exist a subsequence of $\{ (u_m, v_m) \}$ which denote the same, a sequence $(x_m, y_m) \in \mathbb{R}^2$ and $(u^c, v^c) \in M_c$ such that the translated functions

$$(u_m(\cdot + x_m, \cdot + y_m), v_m(\cdot + x_k, \cdot + y_k))$$

converge to $(u^c, v^c)$ strongly in $X$ and $\tilde{d} = d(c) = \frac{1}{3} I_c(u^c, v^c)$.

Proof. The first part of this result is consequence of the Theorem 2.2. Theorem 2.3 and the following argument. Let $(u, v) \in X \setminus \{0\}$ be such that $K_c(u, v) = 0$, then

$$I_c(u, v) = -\frac{3}{2} G(u, v) = -\frac{3}{2} |G(u, v)| = 3 J_c(u, v).$$

Consider the couple

$$(z, w) = \frac{1}{G^{1/3}(u, v)} (u, v).$$

Then $G(z, w) = 1$. Thus,

$$\mathcal{I}_c \leq I_c(z, w) = \frac{1}{G^2(u, v)} I_c(u, v) = \left( \frac{3}{2} \right)^{2/3} I_c^{2/3}(u, v) = \left( \frac{3}{2} \right)^{2/3} \left( 3 J_c(u, v) \right)^{1/3}.$$ 

So that, we concluded

$$\frac{4}{27} I_c^3 \leq d(c).$$

Now, suppose that $(u, v) \neq 0$ such that $G(u, v) = 1$. Take $t$ such that $K_c(tu, tv) = 0$. In this case, $2 I_c(u, v) + 3 t = 0$. Therefore

$$t^2 = \frac{4}{9} I_c^2(u, v).$$

Then we obtain,

$$d(c) \leq J_c(tu, tv) = t^2 (I_c(u, v) + t) = \frac{4}{27} I_c^3(u, v).$$

Thus, we have shown that

$$d(c) \leq \frac{4}{27} \left( I_c \right)^3.$$ 

This proves (3.5). Now, we show the second part. Since $K_c = 2 I_c + 3 G$ then we see that

$$J_c(u_m, v_m) = \frac{1}{3} (I_c(u_m, v_m) + K_c(u_m, v_m)) \to \tilde{d} \leq d(c).$$
Then for $m$ large enough we have that $K_c(u_m, v_m) \leq 0$. This fact implies that
the sequence $\{(u_m, v_m)\}$ is a minimizing sequence for $d(c)$. Then using the part 1
we have that there exist a subsequence of $\{(u_m, v_m)\}$, which denote the same, a
sequence $(x_m, y_m) \in \mathbb{R}^2$ and $(u^c, v^c) \in \mathcal{M}_c$ such that
$(u_m(\cdot + x_m, \cdot + y_m), v_m(\cdot + x_k, \cdot + y_k)) \rightarrow (u^c, v^c)$
in $\mathcal{X}$. In particular $K_c(u^c, v^c) = 0$ and $
\hat{d} = d(c) = \frac{1}{3}I_c(u^c, v^c)$.

**Lemma 3.3.** Let $0 < c < 1$ and $\sigma > 3/8$. Then

1. If $0 < c_1 < c_2 < 1$ and $(u, v) \in \mathcal{N}_c$, then we have that $d(c)$ and $I_{2,c}(u, v)$
are uniformly bounded functions on $[c_1, c_2]$.

2. If $c_1 < c_2$ and $(u^{c_1}, v^{c_1}) \in \mathcal{N}_{c_1}$, we have the following inequalities
$$d(c_1) \leq d(c_2) - \left(\frac{c_2 - c_1}{c_2}\right)I_{2,c_2}(u^{c_2}, v^{c_2}) + o(c_2 - c_1),$$
$$d(c_2) \leq d(c_1) + \left(\frac{c_2 - c_1}{c_1}\right)I_{2,c_1}(u^{c_1}, v^{c_1}) + o(c_2 - c_1).$$

3. If $0 < c_1 < c_2 < 1$, $(u^{c_1}, v^{c_1}) \in \mathcal{N}_{c_1}$ and $I_{2,c_1}(u^{c_1}, v^{c_1}) \leq 0$, then
$$d(c_2) \leq d(c_1) + \left(\frac{2(c_2 - c_1)}{3c_1}\right)I_{2,c_1}(u^{c_1}, v^{c_1}).$$

In particular, $d$ is a strictly decreasing function on $(c_1, 1)$.

**Proof.** (1) Let $c_1, c_2$ be such that $0 < c_1 < c_2 < 1$ and let $(u, v) \in \mathcal{X}$
be such that $G(u, v) \neq 0$. Define $t_c$ by
$$t_c = -\frac{2}{3} \frac{I_c(u,v)}{G(u,v)}.$$ Then we have that $K_c(t_c(u,v)) = 0$ and $J_c(t_c(u,v)) = \frac{4}{3}I_c(u,v)$. Using (2,3) we see that there exist $C > 0$ that depends only on $\sigma$
such that for all $c \in [c_1, c_2]$,
$$d(c) \leq J_c(t_c(u,v)) = \frac{4}{27} \frac{I_c(u,v)}{G(u,v)} \leq C \|/(u,v)\|_X^5.$$ Now, let $(z, w) \in \mathcal{N}_c$, then we have that $2I_c(z, w) + 3G(z, w) = 0$. Moreover,
$$C_1(\sigma, c_1, c_2)\|/(z, w)\|_X^2 \leq 2I_c(z, w) = 3|G(z, w)| \leq C\|/(z, w)\|_X^3.$$ Then we conclude that
$$C_1(\sigma, c_1, c_2) \leq \|/(z, w)\|_X \leq C_2(\sigma, c_1, c_2) \left(\frac{1}{3}I_c(z, w)\right)^{1/2}.$$ Thus, we have shown that
$$d(c) \geq \left(\frac{C_1(\sigma, c_1, c_2)}{C_2(\sigma, c_1, c_2)}\right)^2.$$ Hence, if $(u, v) \in \mathcal{N}_c$ we see that $I_c(u,v)$ and $G(u,v)$ are uniformly bounded on
$[c_1, c_2]$ since
$$d(c) = \frac{1}{3}I_c(u,v) = -\frac{1}{2}G(u,v),$$ which implies that $I_{2,c}(u,v)$ is also uniformly bounded because $K_c(u,v) = 0$ and
$I_1(u,v) \cong \|/(u,v)\|_X^2$. 
(2) Let \((z, w)\) be defined by \((z, w) = t(u^{c_2}, v^{c_2})\). We want \(t\) such that \(K_{c_1}(z, w) = 0\). Note that

\[
K_{c_1}(z, w) = 2t^2 I_{c_1}(u^{c_2}, v^{c_2}) + 3t^3 G(u^{c_2}, v^{c_2})
\]

Thus,

\[
t^2 \left( 2I_{c_2}(u^{c_2}, v^{c_2}) - \frac{2(c_2 - c_1)}{c_2} I_{2,c_2}(u^{c_2}, v^{c_2}) \right) + 3t^3 G(u^{c_2}, v^{c_2})
\]

Thus, \(t\) has to be such that

\[
tG(u^{c_2}, v^{c_2}) = G(u^{c_2}, v^{c_2}) + \frac{2(c_2 - c_1)}{3c_2} I_{2,c_2}(u^{c_2}, v^{c_2})
\]
or equivalently

\[
t = 1 + \frac{2(c_2 - c_1)}{3c_2} \left( \frac{I_{2,c_2}(u^{c_2}, v^{c_2})}{G(u^{c_2}, v^{c_2})} \right) = 1 - \frac{(c_2 - c_1)}{3c_2} \left( \frac{I_{2,c_2}(u^{c_2}, v^{c_2})}{d(c_2)} \right).
\]

Then for this \(t\), we conclude that \(K_{c_1}(z, w) = 0\). Now,

\[
d(c_1) \leq J_{c_1}(u, z) = t^2 \left( I_{c_1}(u^{c_2}, v^{c_2}) + tG(u^{c_2}, v^{c_2}) \right)
\]

\[
= t^2 \left( I_{c_2}(u^{c_2}, v^{c_2}) + \frac{c_1 - c_2}{c_2} I_{2,c_2}(u^{c_2}, v^{c_2}) + tG(u^{c_2}, v^{c_2}) \right)
\]

\[
= t^2 \left( d(c_2) - \frac{c_2 - c_1}{3c_2} I_{2,c_2}(u^{c_2}, v^{c_2}) \right).
\]

But we have that

\[
t^2 = \left( 1 - \frac{(c_2 - c_1)}{3c_2} \left( \frac{I_{2,c_2}(u^{c_2}, v^{c_2})}{d(c_2)} \right) \right)^2
\]

\[
= 1 - \frac{2(c_2 - c_1)}{3c_2} \left( \frac{I_{2,c_2}(u^{c_2}, v^{c_2})}{d(c_2)} \right) + O \left( (c_2 - c_1)^2 \right).
\]

Then we see that

\[
t^2 \left( d(c_2) - \frac{(c_2 - c_1)}{3c_2} I_{2,c_2}(u^{c_2}, v^{c_2}) \right)
\]

\[
= d(c_2) - \frac{(c_2 - c_1)}{c_2} I_{2,c_2}(u^{c_2}, v^{c_2}) + O \left( (c_2 - c_1)^2 \right),
\]

which implies the desired result,

\[
d(c_1) \leq d(c_2) - \frac{(c_2 - c_1)}{c_2} I_{2,c_2}(u^{c_2}, v^{c_2}) + o(c_2 - c_1).
\]

Now, let \((z, w)\) be defined by \((z, w) = t(u^{c_1}, v^{c_1})\). As before, we want \(t\) such that \(K_{c_2}(z, w) = 0\). In this case,

\[
t = 1 - \frac{2(c_2 - c_1)}{3c_1} \left( \frac{I_{2,c_1}(u^{c_1}, v^{c_1})}{G(u^{c_1}, v^{c_1})} \right) = 1 + \frac{(c_2 - c_1)}{3c_1} \left( \frac{I_{2,c_1}(u^{c_1}, v^{c_1})}{d(c_1)} \right).
\]

Since \(K_{c_1}(z, w) = 0\), we see that

\[
d(c_2) \leq J_{c_2}(z, w) = t^2 \left( d(c_1) + \frac{c_2 - c_1}{3c_1} I_{2,c_1}(u^{c_1}, v^{c_1}) \right).
\]

Then, as above, we have that

\[
t^2 = 1 + \frac{2(c_2 - c_1)}{3c_1} \left( \frac{I_{2,c_1}(u^{c_1}, v^{c_1})}{d(c_1)} \right) + O \left( (c_2 - c_1)^2 \right).
\]
Using this we conclude that
\[ t^2 \left( d(c_1) + \frac{(c_2 - c_1)}{3c_1} I_{2,c_1}(u^{c_1}, v^{c_1}) \right) = d(c_1) + \frac{(c_2 - c_1)}{c_1} I_{2,c_1}(u^{c_1}, v^{c_1}) + O \left( (c_2 - c_1)^2 \right), \]
which implies the other inequality.

(3) Assume that \( K_{c_1}(u^{c_1}, v^{c_1}) = 0 \). Hence we see that \( G(u^{c_1}, v^{c_1}) \leq 0 \). Now, if \( I_{2,c_1}(u^{c_1}, v^{c_1}) \leq 0 \) then for \( c_1 < c_2 \) we have that
\[ K_{c_2}(u^{c_1}, v^{c_1}) = K_{c_1}(u^{c_1}, v^{c_1}) + \frac{2(c_2 - c_1)}{c_1} I_{2,c_1}(u^{c_1}, v^{c_1}) \leq 0. \]
Thus, we obtain
\[ d(c_2) \leq \frac{1}{3} I_{2,c_1}(u^{c_1}, v^{c_1}) \]
\[ = \frac{1}{3} \left( I_{c_1}(u^{c_1}, v^{c_1}) + \frac{c_2 - c_1}{c_1} I_{2,c_1}(u^{c_1}, v^{c_1}) \right) \]
\[ \leq d(c_1) + \frac{c_2 - c_1}{3c_1} I_{2,c_1}(u^{c_1}, v^{c_1}). \]
This also implies that \( d(c_2) < d(c_2) \), provided that \( 0 < c_1 < c_2 < 1 \). \( \square \)

**Convexity of \( d \).** Now, we prove that the function \( d \) is strictly convex on \( (c_0, 1) \) with \( c_0 > 0 \) near 1. To do this, we compute \( d' \) and analyze the behavior of \( d \) and \( d' \) near 1. We have the following results.

**Lemma 3.4.** If \( (u^c, v^c) \in G_c \), then we have that
\[ d'(c) = \frac{I_{2,c}(u^c, v^c)}{c}. \] (3.6)

**Proof.** Note that \( d' \) can be computed by taking appropriate limits in part 2 of Lemma 3.3 \( \square \)

**Theorem 3.5.** Let \( \sigma > 3/8 \) and \( (u^c, v^c) \in G_c \). Then we have that
\[ \lim_{c \to 1^-} d(c) = 0 \quad \text{and} \quad I_{2,c}(u^c, v^c) < 0 \quad \text{for } c \text{ near } 1^- \].

**Proof.** From Equations 2.22, 2.24, 2.26 and 3.5 we obtain the first part. Now, using the same notation as Section 2.2, we have
\[ \epsilon I_{2,c}(z^c, w^c) = -c \int_{\mathbb{R}^2} \left( 2z^c \partial_x w^c + \epsilon \partial_x z^c (\partial_{xx} w^c + \epsilon \partial_{xy} w^c) \right) dx dy \]
\[ = -2c \int_{\mathbb{R}^2} (z^c - \partial_x w^c) \partial_x w^c dx dy \]
\[ - \epsilon c \int_{\mathbb{R}^2} \partial_x z^c (\partial_{xx} w^c + \epsilon z^c \partial_{xy} w^c) dx dy - 2c \int_{\mathbb{R}^2} (\partial_x w^c)^2 dx dy. \]
Then using Lemma 2.5, we see that
\[ \lim_{\epsilon \to 0^+} \epsilon I_{2,c}(z^c, w^c) < 0, \]
meaning that for \( \epsilon \) near 0\(^+\) we have \( I_{2,c}(z^c, w^c) < 0 \), which implies that for \( c \) near 1\(^-\), we have \( I_{2,c}(u^c, v^c) < 0 \). \( \square \)
Theorem 3.6. Let $\sigma > 3/8$. Then there exist $0 < c_0 < 1$ such that $d$ is a decreasing function on $(c_0, 1)$. Furthermore, $\lim_{c \to 1^-} d'(c) = 0$.

Proof. Using (3.6) and Theorem 3.5 we have that $d$ is a decreasing function for $c$ near $1^-$ and we also have that $\lim_{c \to 1^-} \| (u^c, v^c) \|_X = 0$ for any $(u^c, v^c) \in X$ such that $d(c) = \frac{1}{3} I_c(u^c, v^c)$, since from (2.3) we see that

$$\| (u^c, v^c) \|^2_X \leq C(\sigma) I_c(u^c, v^c) = C(\sigma) d(c).$$

Thus, from (3.6) and definition of $I_{2,c}$ we conclude that

$$|d'(c)| \leq 2\| u^c \|_{L^2(\mathbb{R}^2)} \| v^c \|_{L^2(\mathbb{R}^2)} + \| u^c_c \|_{L^2(\mathbb{R}^2)} \| \Delta v^c \|_{L^2(\mathbb{R}^2)} \leq 3\| (u^c, v^c) \|^3_X.$$

Therefore, $\lim_{c \to 1^-} d'(c) = 0$. \(\square\)

From the previous results we have the following lemma.

Lemma 3.7. Let $\sigma > 3/8$, then $d$ and $d_1$ are strictly convex for $c$ near $1^{-}$.

We will use the following result by Shatah [14].

Lemma 3.8. Suppose that $h$ is a strictly convex function in a neighborhood of $c_0$. Then given $\varepsilon > 0$, there exist $N(\varepsilon) > 0$ such that for $|c - c_0| = \varepsilon$,

1. If $c_\varepsilon < c_0 < c$ and $|c - c_0| < \varepsilon/2$,

$$\frac{h(c_\varepsilon) - h(c)}{c_\varepsilon - c} \leq \frac{h(c_0) - h(c)}{c_0 - c} - \frac{1}{N(\varepsilon)}.$$

2. If $c < c_0 < c_\varepsilon$ and $|c - c_0| < \varepsilon/2$,

$$\frac{h(c_\varepsilon) - h(c)}{c_\varepsilon - c} \geq \frac{h(c_0) - h(c)}{c_0 - c} + \frac{1}{N(\varepsilon)}.$$

Theorem 3.9. Let $\sigma > 3/8$. If $0 < c_0 < 1$ with $c_0$ near 1 and $(u^{c_0}, v^{c_0}) \in G_{c_0}$, then for $c$ close to $c_0$, there exist $\rho(c) > 0$ such that $\rho(c_0) = 0$ and

$$d(c) - d(c_0) \geq \left( \frac{c - c_0}{c_0} \right) I_{2,c_0}(u^{c_0}, v^{c_0}) + \rho(c).$$

Proof. Let $c < c_0$, $c$ close to $c_0$. Then by Lemma 3.8 for $c < c_0 < c_1$ we see that

$$\frac{d(c) - d(c_1)}{c - c_1} \leq \frac{d(c_0) - d(c_1)}{c_0 - c_1} - \frac{1}{N(c)}.$$

From Lemma 3.3 we have

$$d(c_1) \leq d(c_0) + \left( \frac{c_1 - c_0}{c_0} \right) I_{2,c_0}(u^{c_0}, v^{c_0}) + o(c_1 - c_0).$$

Then we obtain

$$\frac{d(c) - d(c_1)}{c - c_1} \leq \frac{d(c_1) - d(c_0)}{c_1 - c_0} - \frac{1}{N(c)} \leq \frac{I_{2,c_0}(u^{c_0}, v^{c_0})}{c_0} + \frac{o(c_1 - c_0)}{c_1 - c_0} - \frac{1}{N(c)}.$$

Using the continuity of $d$, we have as $c_1 \to c_0$ that

$$\frac{d(c) - d(c_0)}{c - c_0} \leq \frac{I_{2,c_0}(u^{c_0}, v^{c_0})}{c_0} - \frac{1}{N(c)}.$$

As a consequence of this inequality follows that

$$d(c) - d(c_0) \geq \left( \frac{c - c_0}{c_0} \right) I_{2,c_0}(u^{c_0}, v^{c_0}) + \frac{c_0 - c}{N(c)}.$$
Now, let \( c_0 < c \) be \( c \) close to \( c_0 \). If \( c_1 < c_0 < c \), then by using Lemma 3.8

\[
\frac{d(c) - d(c_1)}{c - c_1} \geq \frac{d(c_0) - d(c_1)}{c_0 - c_1} + \frac{1}{N(c)}.
\]

Then from Lemma 3.3

\[
d(c_1) \leq d(c_0) - \left( \frac{c_0 - c_1}{c_0} \right) I_{2,c_0}(u^{c_0}, v^{c_0}) + o(c_1 - c_0).
\]

Thus, we obtain

\[
d(c) - d(c_0) \geq \left( \frac{c - c_0}{c_0} \right) I_{2,c_0}(u^{c_0}, v^{c_0}) + \frac{c - c_0}{N(c)},
\]

and the result follows.

\[\square\]

4. ORBITAL STABILITY OF THE SOLITARY WAVES

We first consider the modulated system associated with the system (2.1) on \( X \). In other words, we assume that the solution \((\eta(t), \Phi(t))\) of the system (1.1) has the form

\[
\eta(t, x, y) = z(t, x - ct, y), \quad \Phi(t, x, y) = w(t, x - ct, y)
\]

Then we see that \((z(t), w(t))\) satisfies the modulated system

\[
\begin{align*}
(I - \frac{1}{2}\Delta)z_t - c(I - \frac{1}{2}\Delta)z_x - & \frac{2}{3}\Delta^2w + \Delta w + \nabla \cdot (z \nabla w) = 0, \\
(I - \frac{1}{2}\Delta)w_t - c(I - \frac{1}{2}\Delta)w_x + z - \sigma \Delta z + & \frac{1}{2} |\nabla w|^2 = 0.
\end{align*}
\]

Observe that the modulated Hamiltonian for this system has the form

\[
\mathcal{H}_c(z, w) = \frac{1}{2} J_c(z, w) = \mathcal{H}(z, w) + \frac{1}{2} I_{2,c}(z, w),
\]

We also observe that \( \mathcal{H}_c \) is conserved in time on solutions since

\[
\begin{align*}
(I - \frac{1}{2}\Delta)z_t = & \partial_w \mathcal{H}_c(z, w) = c \left( I - \frac{1}{2}\Delta \right) z_x + \frac{2}{3} \Delta^2 w - \Delta w - \nabla \cdot (z \nabla w), \\
-(I - \frac{1}{2}\Delta)w_t = & \partial_z \mathcal{H}_c(z, w) = -c \left( I - \frac{1}{2}\Delta \right) w_x + z - \sigma \Delta z + \frac{1}{2} |\nabla w|^2.
\end{align*}
\]

Now we introduce the regions \( \mathcal{R}^1_c, i = 1, 2 \), in the energy space \( X \) by

\[
\mathcal{R}^1_c = \{(z, w) \in X : \mathcal{H}_c(z, w) < \frac{1}{2} d(c), \quad \frac{1}{3} I_c(z, w) < d(c)\}
\]

\[
\mathcal{R}^2_c = \{(z, w) \in X : \mathcal{H}_c(z, w) < \frac{1}{2} d(c), \quad \frac{1}{3} I_c(z, w) > d(c)\}
\]

and have the following result.

**Lemma 4.1.** \( \mathcal{R}^1_c, \mathcal{R}^2_c \) are invariant regions under the flow for the modulated system (4.1).
Proof. Let \((u_0, v_0) \in \mathcal{R}_c^1\). Suppose that \((z(t), w(t))\) satisfies the modulated system (4.1) with initial condition
\[ z(0) = u_0, \quad w(0) = v_0. \]

By characterization of \(d(c)\) and definition of \(\mathcal{R}_c^1\), we must have that
\[ K_c(u_0, v_0) > 0. \]

In fact, suppose that \(K_c(u_0, v_0) \leq 0\). Then we see that \(d(c) \leq \frac{1}{3} I_c(u_0, v_0)\). Moreover, if \((z(t), w(t)) \in \mathcal{R}_c^1\) for some \(t > 0\), we have that \(K_c(z(t), w(t)) > 0\). Now, suppose that there exists a minimum \(t_0\) such that \(K_c(z(t), w(t)) > 0\) for \(t \in [0, t_0)\) and \(K_c(z(t_0), w(t_0)) = 0\). Observe that
\[ d(c) \leq \frac{1}{3} I_c(z(t_0), w(t_0)) \]
\[ \leq \liminf_{t \rightarrow t_0^-} \left( \frac{1}{3} I_c(z(t), w(t)) + \frac{1}{3} K_c(z(t), w(t)) \right) \]
\[ \leq \liminf_{t \rightarrow t_0^-} I_c(z(t), w(t)) \]
\[ \leq 2 \liminf_{t \rightarrow t_0^-} \mathcal{H}_c(z(t), w(t)) \]
\[ \leq 2 \mathcal{H}_c(z_0, w_0) < d(c). \]

This is a contradiction, which shows that \(\mathcal{R}_c^1\) is invariant under the flow for the modulated system (4.1). In a similar fashion we have that \(\mathcal{R}_c^2\) is also invariant under the flow for the modulated system (4.1). \(\square\)

The following lemma will be used to obtain stability with respect to the ground state solutions.

Lemma 4.2. Let \(\sigma > 3/8\) and \(0 < c_0 < 1\) be near 1. If \(U(t) = (\eta(t), \Phi(t))\) is a global solution of the Boussinesq-Benney-Luke system (1.1) with initial condition \(U(0) = U_0 \in \mathcal{X}\), then for every \(M\), there is \(\delta(M)\) such that if
\[ \|U_0 - U^c\|_\mathcal{X} < \delta(M). \]

Then we have
\[ d\left(c_0 + \frac{1}{M}\right) \leq \frac{1}{3} I_c(U(t)) \leq d\left(c_0 - \frac{1}{M}\right), \quad \text{for all } t \in \mathbb{R}. \]

Proof. Let \(M\) be fixed and define \(c_1 = c_0 - \frac{1}{M}\) and \(c_2 = c_0 + \frac{1}{M}\). Now, let \((z^i(t), w^i(t))\) be defined by the formulas
\[ \eta(t, x, y) = z^i(t, x - c_it, y), \quad \Phi(t, x, y) = w^i(t, x - c_it, y), \quad i = 1, 2. \]

Then the couple \((z^i(t), w^i(t))\) satisfies the modulated system (4.1) with initial condition
\[ (z^i(0), w^i(0)) = U(0). \]

For this solution we have that the modulated Hamiltonian is conserved in time, in other words
\[ \mathcal{H}_{c_i}(U(t)) = \mathcal{H}_{c_i}(U(0)). \]

Now, using hypothesis and inequality (2.3) we conclude for small \(\delta\) that
\[ I_{c_i}(U^c) = I_{c_i}(U(0)) + O(\delta). \]
Since $d$ is a strictly decreasing function such that $d(c_0) = \frac{1}{3}I_{c_0}(U^{c_0})$, we can choose $\delta$ small enough in such a way that
\[ d(c_2) < \frac{1}{3}I_{c_0}(U(0)) < d(c_1). \]
We also have that
\[
\begin{align*}
J_{c_i}(U(0)) &= J_{c_i}(U^{c_0}) + O(\delta) \\
&= J_{c_0}(U^{c_0}) + \frac{c_i - c_0}{c_0}I_{2,c_0}(U^{c_0}) + O(\delta) \\
&= d(c_0) + \frac{c_i - c_0}{c_0}I_{2,c_0}(U^{c_0}) + O(\delta) \\
&\leq d(c_1) - \rho(c_i) + O(\delta),
\end{align*}
\]
where we have made use of Theorem 3.9. Next, let $\delta$ be small enough such that
\[ 2\delta < \min\{\rho(c_0 - \frac{1}{M}), \rho(c_0 + \frac{1}{M})\}. \]
This implies
\[ 2\mathcal{H}_{c_i}(U(0)) = J_{c_i}(U(0)) < d(c_i). \] (4.2)

Then, using Lemma 4.1, we have for all $t \in \mathbb{R}$ that
\[ \mathcal{H}_{c_i}(U(t)) < \frac{1}{2}d(c_i), \quad d\left(c_0 + \frac{1}{M}\right) \leq \frac{1}{3}I_{c_0}(U(t)) \leq d\left(c_0 - \frac{1}{M}\right). \]

Finally we establish the main result in this work.

**Theorem 4.3 (Orbital stability).** Let $\sigma > 3/8$ and $0 < c_0 < 1$ be near 1. Then the ground state solitary wave solutions of the Boussinesq-Benney-Luke system (1.1) are stable in the following sense: Given $\varepsilon > 0$, there exist $\delta(\varepsilon) > 0$ such that if $U_0 \in \mathcal{X}$ satisfies
\[ \|U_0 - U^{c_0}\|_X < \delta(\varepsilon), \]
then there exist a unique solution $U(t)$ of the Boussinesq-Benney-Luke system (1.1) with initial condition $U_0$ such that
\[ \inf_{V \in \mathcal{G}_{c_0}} \|U(t) - V\|_X < \varepsilon, \quad \text{for all } t \in \mathbb{R}. \]

**Proof.** We will argue by contradiction. Suppose that there exist a positive number $\varepsilon_0$, and sequences $\{t_k\} \subset \mathbb{R}$ and $\{U_0^k\} \subset \mathcal{X}$, such that
\[ \lim_{k \to \infty} \|U_0^k - U^{c_0}\|_X = 0, \quad \inf_{V \in \mathcal{G}_{c_0}} \|U^k(t_k) - V\|_X > \varepsilon_0, \]
where $U^k$ denotes the unique solution of system (1.1) with initial condition $U^k(0) = U_0^k$. Now, from the Lemma 4.2 and the assumption, given $m > 0$ we have the existence of $\delta(m)$ and a subsequence $k_m$ such that
\[ \|U_0^{k_m} - U^{c_0}\|_X < \delta(m) \]
and
\[ d\left(c_0 + \frac{1}{k_m}\right) \leq \frac{1}{3}I_{c_0}(U^{k_m}(t_{k_m})) \leq d\left(c_0 - \frac{1}{k_m}\right), \]
meaning that there exist a subsequence of \( \{ U^k(t_k) \} \), which we denote the same, such that
\[
d\left(c_0 + \frac{1}{k}\right) \leq \frac{1}{3} I_{c_0} (U^k(t_k)) \leq d\left(c_0 - \frac{1}{k}\right).
\]
In particular, we have that
\[
\frac{1}{3} I_{c_0} (U^k(t_k)) \to d(c_0) \quad \text{as} \quad k \to \infty.
\]
Now, we consider \( c_2 = c_0 + \frac{1}{k} \) and \( V^{k,2}(t) \) defined by
\[
U^k(t, x, y) = V^{k,2}(t, x - c_2 t, y).
\]
Then as in proof of previous lemma (see (4.2)), we obtain that
\[
2H_{c_2} (U^k(t_k)) = J_{c_2} (U^k(t_k)) < d(c_2) < d(c_0) < d\left(c_0 - \frac{1}{k}\right).
\]
On the other hand,
\[
J_{c_2} (U^k(t_k)) = J_{c_0} (U^k(t_k)) + \left(\frac{c_2 - c_0}{c_0}\right) I_{2,c_0} (U^k(t_k))
\]
\[
= J_{c_0} (U^k(t_k)) + \left(\frac{1}{k c_0}\right) I_{2,c_0} (U^k(t_k)).
\]
But note that
\[
\lim_{k \to \infty} \left(\frac{1}{k c_0}\right) \left| I_{2,c_0} (U^k(t_k)) \right| \leq \lim_{k \to \infty} \frac{1}{k} \| U^k(t_k) \|_X^2 \leq \lim_{k \to \infty} \left(\frac{1}{k} C\right) = 0,
\]
since we have that
\[
\| U^k(t_k) \|_X^2 \approx \frac{1}{3} I_{2,c_0} (U^k(t_k)) \to d(c_0).
\]
Using these facts, we conclude that
\[
J_{c_0} (U^k(t_k)) \to d^* \leq d(c_0).
\]
Then by Corollary 3.2 there exist \( U_{c_0} \in G_{c_0} \) such that as \( k \to \infty \),
\[
U^k(t_k) \to U_{c_0} \quad \text{in} \quad X, \quad \frac{1}{3} I_{c_0} (U^k(t_k)) \to d(c_0) = d^*.
\]
also \( J_{c_0} (U^k(t_k)) \to d(c_0) \). But this contradicts the assumption of instability
\[
\inf_{V \in G_{c_0}} \| U^k(t_k) - V \|_X > \varepsilon_0.
\]
